6. The combination in a butter-drilling machine, of a series of drills, means for operating the same, a shaft, a series of bottom-holding checks, disks carried by the shaft and supporting said checks, said checks being arranged in two sets disposed respectively in operative and in inoperative relation to the drills, a spur-gear mounted on the shaft, and a mutilated gear having a series of sets of teeth adapted to engage said spur-wheel and to effect the movement of the sets of checks to alternately present the same to the drills, substantially as specified.

7. In a butter-drilling machine, the series of drills means for operating the same, a shaft, a pair of disks arranged on said shaft, a series of spindles carried by said disks, bottom-holding checks supported by the spindles, intermeshing spindles carried by the spindles, spur-gears carried by one or more of said spindles, a stationary gear-wheel intermeshing with said spur-gear, a spur-gear secured to the shaft, a mutilated gear having a series of sets of teeth adapted to effect a series of movements of the spur-gear through a predetermined distance, and an auxiliary tooth or teeth for effecting a movement of the spur-gear through a less distance, thereby to shift the positions of the bottom-holding checks, substantially as specified.

8. In a butter-drilling machine, means for operating the same, a series of drill-shafts, adjustable supports therefor, means for rotating said drill-shafts, means for moving the same from end toward said bottom-holding checks, and means for successively opening single checks to release the finished bottom, substantially as specified.

9. The combination in a butter-drilling machine, of a series of bottom-holding checks, a pair of dotted disks, means for reciprocating the same, a series of bearing-blanks carried by said disks and adjustable thereon, and drill-shafts adapted to said bearing-blanks, substantially as specified.

10. In a butter-drilling machine, a pair of dotted disks, a series of dotted blanks carried thereby, cut-curves for locking the blanks in an adjusted position, drill-shafts adapted to said blanks, a reciprocating shaft carrying said disk, and means for moving said shaft, substantially as specified.

11. In a butter-drilling machine, the combination with an intermittently-rotative support, of a series of bottom-holding checks carried thereby, a series of drills, means for rotating said drills, means for moving the drills toward and from the bottom-holding checks, a shaft, a disk mounted

thereon, a wrist-pin carried by the disk, and a check-opening lever operatively connected to said pin, substantially as specified.

12. In a butter-drilling machine, the combination of the primary shaft, a movable drill-holding frame, a crank carried by the shaft and operatively connected to said frame, a series of drills mounted in said frame, a rotatable shaft, a pair of supporting-disks thereon, a series of bottom-holding checks carried by the disks, a train of gearing connecting the said shafts, a spur-gear secured to said rotatable shaft, a second shaft, level-gearing connecting the same to the primary shaft, and a mutilated gear on said second shaft and adapted to intermesh with said rotatable shaft, substantially as specified.

699,664. FLOORING-SAW. WILLIAM W. OWEN, Pathe, Ind. Filed May 21, 1891. Serial No. 61,674. (No model.)

Claim.—1. In a gage of the character described, a main bar, a head-piece secured to said bar, said head-piece having a socket, a die which is mounted in said socket and is removable therefrom in the direction of the main bar, a tail-piece mounted to slide upon the main bar, a socket in said tail-piece in which the opposite die is mounted, said die being removable in the direction of the main bar, and means for securing said die in said socket.

2. In a gage of the character described, a main bar, a head-piece secured to said bar, a socket in said head-piece, a die mounted in said socket to determine the form of the edge of a board, said die being removable from the socket in the direction of the length of the main bar, a plate extending into said socket and lying against the surface of the die opposite the main bar to gage the thickness of the board, and means for holding the die and plate in position.

3. In a gage of the character described, a main bar which has a groove throughout the greater part of its length, a head-piece secured to the main bar, a die secured to said head-piece, a tail-piece sliding upon said main bar, a die carried by said tail-piece, and a stop adjustable in said groove to limit the movement of the tail-piece.

4. In a gage of the character described, a main bar, a head-piece secured to said bar, a die carried by said head-piece, a plate for gaging the thickness of the board resting against said die opposite the main bar, said plate being removably secured against said die in order that it may be used with dies made for different thicknesses of boards, a tail-piece slidingly mounted upon the main bar, a die carried by said tail-piece, and a stop adjustably secured to the main bar for limiting the movement of the tail-piece.

5. In a gage of the character described, a main bar provided with a male and a dovetailed groove throughout the greater part of its length, a head-piece secured to said bar, a die carried by said head-piece, a tail-piece mounted for sliding upon the main bar, a die carried by said tail-piece, an adjustable stop having a dovetailed tongue resting in the groove of the main bar, and a cut-over for fixing said stop in any position desired.

6. In a gage of the character described, a main bar which is thicker at its center than at its sides to form a sharp edge, and a male and female die carried by said main bar, the parts being so arranged that when applied to a board the edge on the main bar will fit against the side of the board and the dies will fit its edges.

7. In a gage of the character described, a main bar provided with a male and a dovetailed groove throughout the greater part of its length, a head-piece secured to said bar at one end, a socket in said head-piece, a female die projecting into said socket, a plate for gaging the thickness of the board resting upon the female die, a cut-over for securing the die and plate in the socket, a tail-piece mounted to slide on the main bar, a socket in the tail-piece, a male die projecting into said socket, a partition through the tail-piece separating the main bar and the male die, a cut-over securing the male die in its socket, an adjustable stop carried by said main bar and having a dovetailed tongue entering the groove therein, and a cut-over for fixing the stop in any position desired.

699,665. AUTOMATIC HYDRAULIC FIRE-EXTINGUISHING SYSTEM. JAMES ORRICK, Rockford, Ill. Filed Oct. 19, 1891. Serial No. 71,190. (No model.)

Claim.—1. In a controlling device for a combined wet and dry pipe fire-extinguishing system, the combination with the valve-actuating having an inlet and an outlet, valve-cocks arranged between the inlet and outlet, an air-valve and a water-valve to engage said cocks and held thereby by air-pressure within the dry-pipe system and operably connected to each other, means for holding the air-valve elevated above said cock when the device is used in a wet-pipe system to permit of the free upward movement of the water-valve, and spring-actuated crank-arms arranged below the water-valve and pressing upwardly to augment the force of the inflowing water when the device is used in a dry-pipe system, substantially as set forth.

2. In a controlling device for a combined wet and dry pipe fire-extinguishing system, the combination with the valve-actuating having an inlet and an outlet, valve-cocks arranged between the inlet and outlet, an air-valve and a water-valve to engage said cocks, the water-valve being provided with an upwardly-projecting shank and the air-valve being provided with a downwardly-projecting lug, means for elevating said air-valve from its seat and holding it in such position, an electric alarm, and a lever interposed between the lug and the shank and upon the opening of the valves adapted to permit of the sounding of the alarm, substantially as set forth.

699,666. MATCH-BOX HOLDER. ALFRED H. DOTT, Oconomowoc, Wis. Filed May 14, 1901. Serial No. 60,322. (No model.)

Claim.—A match-box holder adapted to receive a sliding-cover match box, comprising a casing having an opening at the top through which the match-box may be inserted in the holder, a back extending above and below the sides and adapted to be attached to a wall or other support, sides projecting from the back, a front having a central vertical opening adapted to permit the removal of matches from the box, and a bottom having a central transverse opening extending to the back.

699,667. DRAWING MECHANISM FOR MIXING-MACHINE VEHICLES OR THE LIKE. GEORGE T. DRAKE, Chicago, Ill. Filed June 7, 1901. Serial No. 61,304. (No model.)

Claim.—1. The combination with a vehicle, of parallel shafts journaled above the body of said vehicle, drums fixed upon said shafts, a stationary cable a portion of which passes through the body of the vehicle and around said drums a plurality of times, guide-rollers engaged by the cable suspended beneath the body of the vehicle, a power-shaft also jour-

nalled upon the body of the vehicle and parallel with said drum-shafts, speed-reducing connections between said power-shaft and one of said drum-shafts for driving the latter, connections between said drum-shafts whereby the rotation of one affects the rotation of the other, a motor mounted on the vehicle, and speed-reducing gearing operatively connecting said motor to said power-shaft.

2. The combination with a vehicle, of parallel shafts journaled above the body of said vehicle, drums fixed upon said shafts, a stationary cable a portion of which passes through the body of the vehicle and around said drums, guide-rollers engaged by the cable suspended beneath the body of the vehicle, a power-shaft also journaled upon the body of the vehicle and parallel with said drum-shafts, connections between said power-shaft and one of said drum-shafts for driving the latter, connections between said drum-shafts whereby the rotation of one affects the rotation of the other, a motor mounted upon the vehicle, power connections between said motor and said power-shaft, and means for reversing the direction of rotation of said power-shaft whereby the vehicle may be propelled in either direction.

3. The combination with a vehicle, of parallel shafts journaled above the body of said vehicle, drums fixed upon said shafts, a stationary cable a portion of which passes through the body of the vehicle and around said drums, guide-rollers engaged by the cable suspended beneath the body of the vehicle, a power-shaft also journaled upon the body of the vehicle and parallel with said drum-shafts, connections between said power-shaft and one of said drum-shafts for driving the latter, connections between said drum-shafts whereby the rotation of one affects the rotation of the other, a shaft-shaft rotating at right angles to said power-shaft with which it is operatively connected, a second shaft-shaft parallel with the first, shaft-shaft, a motor mounted upon the vehicle and operatively connected to said second shaft-shaft, and means interposed between said shaft-shafts whereby the former may be rotated in either direction.

4. The combination with a vehicle, of standards mounted upon and projecting above the body thereof, shafts journaled in said standards, a power-shaft also journaled in said standards parallel with said first-mentioned shafts, speed-reducing gears between said power-shaft and said first-mentioned shafts, drums fixed upon said shafts, brackets secured to and depending below the body of said vehicle, guide-rollers journaled in said brackets, other guide-rollers between said shafts and said first-mentioned guide-rollers, and a stationary cable passing around said guide-rollers, through the body of the vehicle and around said drums a plurality of times.

699,668. APPARATUS FOR MIXING CONCRETE. GEORGE T. DRAKE, Chicago, Ill. Filed Nov. 14, 1901. Serial No. 61,728. (No model.)

Claim.—1. In an apparatus of the character described, the combination with a mixer, of longitudinal parallel beams upon which the mixer is supported, beams secured to and depending from said longitudinal beams, a horizontal frame supported beneath the discharging end of the mixer,

by said depending beams, and a conveyor mounted upon said horizontal frame.

2. In an apparatus of the character described, the combination with a mixer, of longitudinal parallel beams upon which the mixer is supported, beams secured to and depending from said longitudinal beams, a horizontal frame supported beneath the discharging end of the mixer by said depending beams, a turn-table rotatably mounted upon said horizontal frame, and a vertically-rotating conveyor pivoted to said turn-table.

3. In an apparatus of the character described, the combination with a mixer, of a support therefor, a discharge-chute located beneath the delivery end of said mixer and mounted upon said support, a cylindrical guide-roller journaled upon said support beneath said chute, a conveyor-frame pivotedly mounted on said support, a cylindrical guide-roller journaled in the outer end of said frame, concave guide-rollers journaled in said conveyor-frame, a conveyor-belt passing around said cylindrical and concave guide-rollers, and a funnel-shaped hopper supported by said conveyor-frame below the cylindrical guide-roller journaled in the end thereof.

4. In an apparatus of the character described, the combination with a mixer, of a support therefor, a horizontally-rotating conveyor-frame mounted upon said support, a conveyor-belt carried by said frame, a chute horizontally movable with said conveyor-frame and receiving the material from the mixer and depositing the same upon the conveyor-belt, and concave guide-rollers journaled in said conveyor-frame over which said belt passes, substantially as described.

5. In an apparatus of the character described, the combination with a mixer, of a support therefor, a horizontally-rotating conveyor-frame mounted upon said support, a conveyor-belt carried by said frame, a chute horizontally movable with said conveyor-frame and receiving the material from the mixer and depositing the same upon the conveyor-belt, and concave guide-rollers journaled in said conveyor-frame over which said belt passes, substantially as described.

6. In an apparatus of the character described, the combination with a mixer, of a support therefor, a horizontally-rotating conveyor-frame mounted upon said support, a conveyor-belt carried by said frame, a chute horizontally movable with said conveyor-frame and receiving the material from the mixer and depositing the same upon the conveyor-belt, concave guide-rollers journaled in said conveyor-frame over which said belt passes, and a funnel-shaped hopper supported by said conveyor-frame below the delivery end thereof, substantially as described.

7. In an apparatus of the character described, the combination with a support, of a vertically-rotating conveyor-frame mounted on said support, a conveyor-belt carried by said frame, transversely-rotating shafts secured to the sides of said frame, bearings on said support within which said shafts are received, a shaft extending through said bearings, bushings secured to said shaft and interposed between the same and said shafts,

means for rotating said shaft, and means connecting said shaft with said conveyor-belt for driving the latter, substantially as described.

8. In an apparatus of the character described, the combination with a support, of a horizontally-rotating conveyor-frame, a conveyor-belt carried by said frame, a turn-table mounted upon said support to which said conveyor-frame is connected, a king-bolt passing through said support and said turn-table, a gear-wheel the axis of which is in alignment with the king-bolt, a support for said gear-wheel secured to said turn-table and interposed between said gear-wheel and king-bolt, a power-shaft operatively connected with said gear-wheel, and means connecting said gear-wheel with said belt whereby the latter is driven, substantially as described.

9. In an apparatus of the character described, the combination with a support, of a horizontally-rotating conveyor-frame, a conveyor-belt carried by said frame, a turn-table mounted on said support to which said conveyor-frame is pivoted, a king-bolt passing through said support and said turn-table, a double gear-wheel having teeth on its upper and lower faces the axis of which is in alignment with said king-bolt, a power-shaft having a gear-wheel in mesh with the teeth on one face of said double gear-wheel, a shaft-shaft having a gear-wheel in mesh with the teeth on the other face of said double gear, and means connected to said shaft-shaft for driving the conveyor-belt, substantially as described.

699,669. TOY JACK-O'-LANTERN. JOHN J. DE KAY, Toledo, Ohio. Filed May 12, 1901. Serial No. 60,897. (No model.)

Claim.—1. In a toy jack-o'-lantern, the combination of a hollow spheroidal body, comprising continuous provided with rim extensions adapting the sections to be telescopically joined to form the whole; a ball coincident through the joined rims at opposite points above the center of gravity of the lantern-body; a ball provided with a central stem for a handle, and having arms curved to cradle the body of the lantern, and the ends of the arms angled inward and adapted to be inserted in the ball-sockets to lock the sections against disjoining and pivotally support the lantern-body; a candle-socket within the lantern-body secured by its base to one of the sections below the center of gravity and at right angles to the pivotal axis and adapted to be held normally vertical by gravity; ventilating-cribs in the lantern-body at the base and opposite the top of the candle-socket; apertures cut through the wall of the body, and translucent coverings for the apertures.

2. In a toy jack-o'-lantern, the combination of a hollow spheroidal body comprising continuous provided with rim extensions, adapting the sections to be telescopically joined to form the whole; cribs for a ball coincident through the joined rims at opposite points above the center of gravity of the lantern-body; a ball provided with a central stem for a handle, and having arms curved to cradle the body of the lantern and the ends of the arms angled inward and adapted to be inserted in the ball-sockets to lock the sections against disjoining, and pivotally support the lantern-body; cribs through the lantern-body at diametrically opposite points at right angles to the pivotal axis, adapted to be brought, one vertically above and the other vertically below the axis by gravity; a candle-socket adapted to be inserted in the cribs normally below the axis, said socket having an elastic base adapted to be compressed by such insertion and frictionally secure the socket within the lantern-body; apertures cut through the wall of the body and translucent coverings for the apertures.

3. In a toy jack-o'-lantern, the combination of a hollow spheroidal body comprising continuous provided with rim extensions, adapting the sections to be telescopically joined to form the whole, a segment of one of said sections being cut away parallel with the plane of its rim and a translucent, flame-proof sheet fitted over the opening thus made in the section; cribs for a ball coincident through the joined rims at opposite points above the center of gravity of the lantern-body; a ball provided with a central stem for a handle, and having arms curved to cradle the body of

the lantern and the ends of the arms angled inward and adapted to be inserted in the ball-sockets to lock the sections against disjoining, and pivotally support the lantern-body; crutons through the lantern-body at diametrically opposite points at right angles to the pivotal axis, adapted to be brought, one vertically above and the other vertically below the axis by gravity; and a candle-socket adapted to be inserted in the cruton normally below the axis, said socket having an elastic base adapted to be compressed by each insertion and frictionally secure the socket within the lantern-body.

699,670. CIGAR-VENDING MACHINE. WILLIAM R. DUTCHER, Auburn, R. I. Filed Jan. 9, 1908. Serial No. 64,886. (No model.)

Claim.—1. In a cigar-vending machine, the combination of a magazine having a receptacle at its lowermost portion arranged to receive a single cigar; an actuating device arranged to direct a cigar into said receptacle; an ejector arranged to enter the receptacle and move a cigar outwards therefrom; and means for preventing movement of the actuating device while the ejector is located in the said receptacle.

2. In a cigar-vending machine, the combination of a magazine having a substantially V-shaped bottom that is provided with one or more slots extending transversely to the line of convergence of the walls forming the V-shaped bottom; an actuating-lever operating in each slot; each lever having a depression in its upper edge that is in alignment with the said line of convergence when the lever is in its normal position; and means for ejecting a cigar from the angular portion of the magazine.

3. In a cigar-vending machine, the combination of a magazine having a substantially V-shaped bottom that is provided with one or more slots extending transversely to the line of convergence of the walls forming the V-shaped bottom; an actuating-lever *d*, operating in each slot; said lever having a depression *d'*, in its upper edge that is in alignment with the said line of convergence when the lever is in its normal position; the lever also having the corrugation *d''*, adjacent the depression *d'*, and the extended portion *d'''*; and means for moving a cigar from the angular portion of the magazine.

699,671. COMBINED WHEEL-HOIST, WHEEL-REST, TRIMMER, SCRAPER, BUT-GLITCH, &c. CHARLES H. PARKER, Christiansburg, Va. Assignor of one-third to Margaret Hartwell Stuart, Longwood, Cal. Filed Feb. 6, 1901. Serial No. 64,886. (No model.)

Claim.—1. In a wheel-hoist the combination of a standard, a screw-rod slidably mounted therein, a nut carried on said screw-rod, a lever mounted at one end on said standard, and links connecting said nut and lever all substantially as set forth.

2. A wheel-hoist consisting of a standard, a double-bar lever pivoted at one end to opposite sides thereof, means carried by said lever for holding the latter in an elevated position, an adjustable screw-rod slidably in said standard, a nut carried by said screw-rod, links pivotally connected to said nut and lever, and a wheel-rest horizontally supported by the upper portion of said screw-rod, all substantially as set forth.

3. A wheel-hoist consisting of a standard, an adjustable screw-rod slidably therein, a nut carried on said screw-rod, a double-bar lever pivoted to opposite sides of said standard, links connecting said nut and lever having a plate slidably thereon said plate having an aperture therein adapted to fit over the upper end of said screw-rod to hold the lever in elevated position and a wheel-rest horizontally supported by the upper portion of the said screw-rod, all substantially as set forth.

4. A wheel-hoist consisting of a standard, a double-bar lever pivoted to opposite sides thereof, means carried by said lever for holding the latter in an elevated position, an adjustable screw-rod slidably in said standard, a nut carried by said screw-rod, links pivotally connected to said nut and lever, and a wheel-rest having a sharp upper edge thereon, horizontally supported by the upper portion of said screw-rod, all substantially as set forth.

5. A wheel-hoist consisting of a standard, a double-bar lever pivoted at one end to opposite sides thereof, means carried by said lever for holding the latter in elevated position, an adjustable screw-rod slidably in said standard, a nut carried by said screw-rod, links pivotally connected to said nut and lever, and a wheel-rest having means at its outer end to receive and support the end of a vehicle-spindle and horizontally supported by the upper portion of said screw-rod, all substantially as set forth.

6. A device of the character described comprising a standard, a rod slidably therein, means for adjusting said rod, a support horizontally held by the upper portion of said rod, a ring rotatably mounted on said support, two bars pivoted to opposite sides of said ring and means for clamping the free ends of said bars together, all substantially as set forth.

7. A wheel-hoist comprising a base-plate, a hollow standard supported thereby, a collar fixed to said standard, a screw-threaded rod slidably mounted in said standard and having a projection at its upper end, a threaded nut mounted upon said rod, a double-bar lever pivotally connected at one end with said collar links pivotally connected to said nut and to said lever intermediate its ends, a latch for said lever consisting of a plate slidably thereon and having an aperture adapted to fit over the projection upon the screw-rod in order to hold the lever and thereby the screw-rod in elevated position, said rod having a transverse aperture near its upper end, a wheel-rest horizontally carried by said rod and consisting of a thin flat bar, one end of which is adapted to enter the aperture in the screw-rod, a support carried by said bar, said support having means at its outer end to receive the threaded end of a vehicle-spindle, all substantially as set forth.

699,672. SPINNING-MACHINE. JOHN A. FREDERICK, Reading Pa. Filed May 28, 1901. Serial No. 64,886. (No model.)

Claim.—1. The combination with a tube having a pocket therein; of a grooved die seated within the tube; a vertically-movable die thereabove; a stem to said die; a spring including the said stem and adapted to hold the die normally in contact; arms to the stem; and a cam including said stem and normally contacting with the arm, said cam being adapted to raise the stem and its die.

2. In a device of the character described, the combination with a

tube having a pocket therein, of a grooved die seated within the pocket, independent vertically-movable die thereon, means for holding said die normally in contact with the grooved die and means for raising the movable die simultaneously.

3. In a device of the character described, the combination with a tube having a pocket therein; of a grooved die seated within the pocket, independent vertically-movable grooved die thereon, springs for holding said die in contact with the die in the pocket, and means for raising the movable die simultaneously.

4. In a device of the character described, the combination with a tube having a pocket therein; of a grooved die seated within the pocket, vertically-movable independent grooved die thereover, stems to said independent die, springs thereon for holding said die normally in contact with the die in the pocket, a rotatable cam, and means operated by the cam for raising the stems and their die, simultaneously.

699,673. TAKE-UP FOR SEWING-MACHINE. WILLIAM C. PARK, Chicago, Ill. Filed Oct. 21, 1901. Serial No. 78,428. (No model.)

Claim.—1. In a take-up mechanism for sewing-machine, in combination, a take-up lever provided with a thread-eye, a vertically-movable presser-bar, a bracket fixed to the presser-bar and arranged to reciprocate vertically therewith, a slack-thread-controlling lever, mounted on the bracket on the presser-bar and provided, at its free end, with a thread-eye, means for actuating the take-up lever and means for reciprocating the presser-bar, substantially as and for the purpose specified.

2. In a take-up mechanism for sewing-machine, in combination, a driving-shaft, a wheel—fast thereto—having a circumferential cam-groove therein adapted to engage and operate a take-up lever, a take-up lever engaged, at one end, by the circumferential groove in the wheel, and provided, at its other end, with a thread-eye, a vertically-movable presser-bar, a bracket fixed to the presser-bar and arranged to reciprocate vertically therewith, a slack-thread spring-actuated controlling-lever mounted on the bracket on the presser-bar and provided, at its free end, with a thread-eye, and bearings, in the machine-frame, for operatively supporting all of said parts, substantially as and for the purpose specified.

699,674. CIGAR-SMOKING MACHINE. WILLIAM H. GARDNER, Canton, R. I. Filed Aug. 3, 1901. Serial No. 78,428. (No model.)

Claim.—1. In a cigar-smoking machine, the combination with a tobacco-feeding mechanism, a magazine communicating therewith, and a plunger arranged to advance the tobacco in the magazine, of means for causing the plunger mechanism to vary the action of the feeding mechanism.

2. In a cigar-smoking machine, the combination with a tobacco-feeding mechanism, a magazine communicating therewith, and a plunger arranged to advance the tobacco in the magazine, of means for causing the plunger mechanism to retard the normal action of the feeding mechanism when the tobacco in the magazine exceeds a predetermined quantity.

3. In a cigar-smoking machine, the combination with a tobacco-feeding mechanism, a magazine communicating therewith, and a plunger arranged to advance the tobacco in the magazine, of means for causing the plunger mechanism to retard the feeding mechanism temporarily inoperative when the tobacco in the magazine exceeds a predetermined quantity.

4. In a cigar-smoking machine, the combination with a tobacco-feeding mechanism, a magazine communicating therewith, and a plunger

arranged to advance the tobacco in the magazine, of means for causing the plunger mechanism to retard the normal action of the feeding mechanism when the tobacco in the magazine exceeds a predetermined quantity, and means for adjusting said latter means to vary said predetermined quantity.

5. In a cigar-smoking machine, the combination with an intermittent vertically-movable tobacco-feeding mechanism, a magazine communicating therewith, and a plunger arranged to advance the tobacco in the magazine, of means connected with the plunger mechanism for causing the feeding mechanism to omit one or more steps in its intermittent movement when the tobacco in the magazine exceeds a predetermined quantity.

6. In a cigar-smoking machine, the combination with a feeding device provided with a ratchet-wheel through which power is transmitted to actuate the device, an oscillating pawl having an invariable angular movement and arranged to engage said wheel, and a gage-rod arranged to be normally in the path of said pawl and engage with and strip said pawl, a magazine, a plunger arranged to press the tobacco ahead in the magazine, the plunger being arranged to move the gage-rod out of position of engagement with said pawl when the quantity of tobacco in the magazine extends to a predetermined point.

7. In a cigar-smoking machine, the combination with a feeding device provided with a ratchet-wheel through which power is transmitted to actuate the device, an oscillating pawl having an invariable angular movement and arranged to engage said wheel, and a gage-rod arranged to be normally in the path of said pawl and engage with and strip said pawl, a magazine, a plunger arranged to press the tobacco ahead in the magazine, means for causing the plunger to engage with and thereby advance and retract the gage-rod at its forward and rearward positions respectively, and means for adjusting the said position of engagement.

8. In a cigar-smoking machine, the combination of a tobacco-feeding device, a ratchet-wheel through which the device is adapted to be rotated in one direction only, an oscillating pawl moving an invariable angular distance back and forth at each revolution of the machine, a magazine, a plunger arranged to press the tobacco in the magazine, means for moving the plunger, a rod having the plunger secured to its front end and carrying an arm, an end-wise-movable gage-rod passing loosely through the said arm, a collar secured to the rod on each side of said arm, the collar being arranged whereby the plunger in its forward movement causes said arm to engage one of the collars and advance the gage-rod into a position to engage with and move the said pawl downwardly onto the wheel and then rotate the latter on the return movement of the pawl and thereby actuate the feeding device, the other collar being so arranged that on the rearward movement of the plunger said arm will engage this collar and thereby return the gage-rod to its normal or non-operative position.

9. In a cigar-smoking machine, a tobacco-feeding device provided with a ratchet-wheel through which the device is operated, an oscillating arm carrying a spring, a spring-pressed pawl mounted in the outer end of said arm and arranged to engage the teeth of said wheel, a notched latch connected with and moving in unison with the pawl and arranged to receive the free end of said spring at its notch, a fixed stop arranged to engage with and detach the spring from the notched portion of said latch just before said arm and attached parts complete the forward stroke, thereby permitting the pawl to swing upwardly out of engagement with the wheel, and an automatically-actuated gage-rod located in the path of the pawl, and so arranged that the pawl in its rearward movement strikes the rod and is moved downward into engagement with the ratchet-wheel whereby said spring is permitted to enter the notched part of the latch.

699,675. WINDING. ALBERT F. SMITH, Redwood, N. H. Filed Sept. 21, 1901. Serial No. 78,427. (No model.)

Claim.—1. The combination with a shank, having a head or socket at one end and at the opposite end a bearing-plate, of a movable jaw or spoke-grip having an elongated slot whereby the same is slidably secured to said shank through the medium of a headed bolt, a hook at one end of said jaw or spoke-grip to partially enclose a spoke, a finger-grip at the opposite end of said jaw or spoke-grip to adjust the same; and a cam-faceted lever to secure said jaw in its adjusted position.

2. The combination with a shank, having a head or socket at one end and at the opposite end a bearing-plate, of a movable jaw or spoke-grip having an elongated slot whereby the same is slidably secured to said shank through the medium of a headed bolt, a hook at one end of said jaw or spoke-grip to partially enclose a spoke, a finger-grip at the opposite end of said jaw or spoke-grip to adjust the same, and a cam-faceted lever mounted on said bolt and provided with a handle to facilitate said lever to bring the cam portion thereof under the head of said bolt to head the said jaw against the shank, locking it in its adjusted position.

3. A wrench comprising a shank having a downwardly and outwardly curved portion and a straight portion, a head or socket having tapering inner walls secured to outwardly-curved portion, a rectangular opening in said portion, a bearing-plate secured to said straight portion, a movable jaw having an elongated slot whereby the same is slidably secured to said shank upon a head-bolt, a curved portion on one end of said jaw, a finger-grip on the opposite end thereof, a cam-faceted lever eccentrically mounted on said bolt whereby the jaw is secured in its adjusted position, and means for preventing the parts that come in contact with the wheel from scratching the same, substantially as shown and described.

699,676. TELEPHONE-CIRCUIT. GEORGE R. COWMAN, Worcester, Mass. Filed June 14, 1903. Serial No. 20,393. (No model.)

Claim.—1. In a telephone circuit or system, a switch, comprising two contact-plates having connection with the main line, a movable contact-plate adapted for engagement with either one of the first-named contact-plates, a receiver-hook and a shifting rod extended from said movable contact-plate and having a loop through which the receiver-hook passes, whereby said receiver-hook may move upward without imparting motion to the rod, the said receiver-hook operating to close the calling-circuit when moved downward, substantially as specified.

2. In a telephone circuit or system, two contact-plates arranged within a telephone-box and having connection with the main line, a movable contact-plate adapted to be engaged with either one of said first-named contact-plates and adapted to interlock therewith, a swinging blank on which the movable contact-plate is mounted, a receiver-hook, and a shifting rod extended from said blank down the outer side of the box and having a loop portion through which the receiver-hook passes, the said receiver-hook causing the closing of the calling-circuit when moved downward, substantially as specified.

3. In a telephone, a circuit-changer comprising contact-plates connected with the main circuit, a movable contact-plate adapted for engagement with either one of the first-named contact-plates, a receiver-hook, a shifting rod extended from the movable contact-plate, and a loop on the end of said shifting rod, through which the receiver-hook of the telephone passes and in which the said hook may move upward without imparting motion to the rod, but upon a downward motion of which will shift the rod to close the ringing-circuit, substantially as specified.

4. In a telephone system, circuits leading in opposite directions from a telephone, a receiver-hook on the telephone, contacts closed for one line by the upward movement of the hook, and contacts in the opposite line closed upon a downward movement of said hook, substantially as specified.

699,677. MEDICAL BATTERY. FREDERICK GUNN, Chicago, Ill. Filed Sept. 27, 1900. Serial No. 731,874. (No model.)

Claim.—1. In a medical battery, in combination, an insulating case containing a cell having a contact-spring secured to its negative pole; a base-plate carrying a coil on one of its surfaces; and two contact-springs on the other surface of said base-plate, respectively adapted to engage the contact-spring of the negative pole of the cell and the lining of said coil.

2. In a medical battery, in combination, a battery comprising a plurality of cells; a coil; a base-plate carrying said coil on its upper surface; a contact-spring secured to the lower surface of said base-plate, for each of said cells, for making electrical connection between the casing of said coil and the line of the cell; and a contact-spring projecting downward from the lower face of said base-plate, for each of said cells, for making electrical connection between one of the poles of said coil and the line of the cell.

3. In a medical battery, in combination, a battery comprising a plurality of cells, each cell being provided with a contact-spring secured to its negative pole; a coil; a switch; a base-plate carrying said coil and said switch on its upper surface; a contact-spring secured to the lower surface of said base-plate, for each of said cells, for making electrical connection between the casing of said coil and the line of the cell; a contact-spring projecting downward from the lower face of said base-plate, for each of said cells, for making electrical connection between the contact-spring secured to the negative pole of said coil and the line of the cell.

699,678. STAY-BOLT AND PROCESS OF MAKING SAME. GUS O. GRIMLEY, Windsor, Vt. Filed May 24, 1906. Serial No. 17,807. (No model.)

Claim.—1. The herein-described method of making a stay-bolt for bolters which consists in simultaneously rolling the threads at both ends of the said stay-bolt and thereby making said threads continuous of each other and forming on the said bolt a surface or skin which is compressed or compressed.

2. The herein-described method of making a stay-bolt for bolters which consists in upsetting the ends of a cylindrical blank, and simultaneously rolling the threads on the said upset ends, whereby said threads are continuations of each other.

3. The herein-described method of making a stay-bolt for bolters, which consists in simultaneously upsetting and preparing an end of a suitable blank for a tool for forming it, and then threading the said upset end.

4. The herein-described method of making stay-bolts for bolters, which consists in providing a cylindrical blank, upsetting the ends thereof, and simultaneously rolling threads on the two ends of the partially-upset stay-bolt, whereby the threads thereon are practically continuations of each other, and the surface or skin of the threaded part is compressed or compressed.

5. The herein-described method of making stay-bolts for bolters, consisting in providing a suitable cylindrical blank, simultaneously upsetting an end and punching a hole in the said end of the said blank, and then rolling threads on the upset end.

6. As a new article of manufacture, a stay-bolt for bolters having threads rolled on its ends whereby the surface of said ends is compressed or compressed, the threads on one end being continuations of the threads on the other end.

7. As a new article of manufacture, a stay-bolt for bolters having upset ends, and threads simultaneously rolled on said ends, whereby the said surfaces of the said ends are compressed or compressed, and the threads thereon are continuations of each other.

8. As a new article of manufacture, a stay-bolt for bolters having its ends larger than its middle, and having threads rolled on said ends whereby the surface of said ends are compressed or compressed.

9. As a new article of manufacture, a stay-bolt for bolters having its ends upset and longitudinally apertured by a punching process, said apertures projecting into the body of the said bolt beyond the upset ends, said stay-bolt having the said upset ends provided with threads which are rolled thereon and which are in effect continuous.

699,679. STITCH-SEPARATING MACHINE. JOHN R. HAMMILL, Boston, Mass. Filed Mar. 6, 1901. Serial No. 49,941. (No model.)

Claim.—1. A stitch-separating machine, having, in combination, a work-support, an indexing-tool provided with an indexing portion and with a shaping and polishing portion, means for actuating the tool to indent the work, and means independent of the work for imparting to the tool a shaping and polishing oscillating movement while in engagement with the work, substantially as described.

2. A stitch-separating machine, having, in combination, a work-support, an indexing-tool provided with an indexing portion and with a shaping and polishing portion, means for actuating the tool to indent the work, and means independent of the work for imparting to the tool a shaping and polishing oscillating movement while in engagement with the work, substantially as described.

3. A stitch-separating machine, having, in combination, a work-support, an indexing-tool provided with an indexing portion and with a shaping and polishing portion, means for actuating the tool to indent the work, means for actuating the tool to feed the work, and for simultaneously imparting to the tool a shaping and polishing oscillating movement, substantially as described.

4. A stitch-separating machine, having, in combination, a work-support, an indexing-tool provided with an indexing portion and with a shaping and polishing portion, means for actuating the tool to indent the work, and means for imparting to the tool a shaping and polishing oscillating movement to feed the work, substantially as described.

5. A stitch-separating machine, having, in combination, a work-support, an indexing-tool, means for actuating the tool to indent the work, and means for oscillating the tool about an axis below the plane of the surface of the work to feed the work, substantially as described.

6. A stitch-separating machine, having, in combination, a work-support, an indexing-tool provided with an indexing portion and with a shaping and polishing portion, means for actuating said tool toward and from its axis of oscillation, means for adjusting for imparting to the tool a shaping and polishing oscillating movement to feed the work, substantially as described.

7. A stitch-separating machine, having, in combination, an indexing-tool provided with an indexing portion and with a shaping and polishing portion, a work-support arranged to allow the work to shift under the action of the tool, means for actuating the tool to indent the work and means independent of the work for imparting to the tool a shaping and polishing oscillating movement to cause the tool to act successively on different portions of the work, substantially as described.

8. A stitch-separating machine, having, in combination, an indexing-tool, a yielding-mounted work-support, means for actuating the tool to indent the work, means for oscillating the tool to feed the work, and means for locking the work-support during the indexing and feeding movements of the tool, substantially as described.

9. A stitch-separating machine, having, in combination, a work-support, a two-pointed indexing-tool, means for actuating the tool to come one of the points to indent a stitch interval and means independent of the work for oscillating the tool to cause the other point to indent the next adjacent stitch interval, substantially as described.

10. A stitch-separating machine, having, in combination, a work-support, an indexing-tool, means for oscillating the tool to feed the work, means for yieldingly pressing the tool against the work during a portion of its feeding movement, and means for positively pressing the tool against the work during the remainder of its feeding movement, substantially as described.

11. A stitch-separating machine, having, in combination, a work-support, a tool-carrier, an indexing-tool carried thereby, means for actuating the tool-carrier to bring the tool into engagement with the work, and mechanism for oscillating the tool on the tool-carrier to feed the work, substantially as described.

12. A stitch-separating machine, having, in combination, a work-support, a two-pointed indexing-tool, means for actuating the tool to indent the work and means independent of the work for oscillating the tool while in engagement with the work, substantially as described.

13. A stitch-separating machine, having, in combination, a work-support, an oscillating indexing-tool provided with an indexing portion and with a shaping and polishing portion having its working face set off from its axis of oscillation and means independent of the work for imparting to the tool a shaping and polishing oscillating movement, substantially as described.

699,680. PNEUMATIC SHOVEL. LAFAYETTE HAMMILL, Mable Springs, and WILLIAM C. DAVIS, Denver, Colo. Filed Dec. 12, 1901. Serial No. 60,716. (No model.)

Claim.—1. In a power-shovel, a carrying-truck, a two-table mount of thereon, guides on said turn-table, arms slidingly and pivotally supported from said guides, a shovel carried by said arms, means for advancing and retracting said arms, and means connected to said arms for raising and lowering them, substantially as described.

2. In a power-shovel, a carrying-truck, guides carried thereby, a yoke having members sliding in said guides, means for reciprocating said yoke, arms pivoted to said members and carrying a shovel at their forward ends, and means connected to said arms for swinging them upwardly, substantially as described.

3. In a power-shovel, a carrying-truck, guides carried thereby, a yoke having members sliding in said guides, means carried directly by the truck for reciprocating the yoke, arms having their rear ends pivoted to said yoke members, and carrying a shovel at their forward ends, and means connected to said arms for raising and lowering them, substantially as described.

4. In a power-shovel, a carrying-truck, guides carried thereby, a yoke having side members sliding in said guides, arms having their rear ends pivotally connected with said yoke members, and carrying a shovel at their forward ends, means carried by said truck between the guides for reciprocating the yoke, and means supported by the truck above the reciprocating means for raising and lowering the arm, substantially as described.

5. In a power-shovel, a carrying-truck, guides carried thereby, arms having their rear ends provided with a sliding connection with said guides, a shovel carried on the front ends of said arms, a pneumatic cylinder and piston for reciprocating said arms, and a pneumatic cylinder and piston for raising and lowering said arms, substantially as described.

6. In a power-shovel, a carrying-truck, guides carried thereby, a yoke having members sliding in said guides, a pneumatic cylinder and piston for reciprocating said yoke, arms having their rear ends pivoted to said yoke members and carrying a shovel at their forward ends, and a pneumatic cylinder and piston for raising and lowering said arms, substantially as described.

7. In a power-shovel, a carrying-truck, guides carried thereby, a yoke having members sliding in said guides, a pneumatic cylinder and piston for reciprocating said yoke, arms having their rear ends pivoted to said yoke members and carrying a shovel at their forward ends, a lifting-cylinder and piston supported by said truck, movable sheaves operated by said piston, stationary sheaves suitably supported, and chains having each one end connected to the pivoted arms and the other connected to a rigid part of the frame, substantially as described.

8. In a power-shovel, a truck, a yoke having members supported thereby to have longitudinal movement, means for moving said yoke, arms pivoted to said members and carrying a shovel at their forward ends, quadrants secured to said arms, stationary and movable sheaves, chains secured to said quadrants and passing around said stationary and movable sheaves, the opposite ends of said chains being secured to a fixed part of the frame, and means for moving said movable sheaves to elevate the arms, substantially as described.

9. In a power-shovel, a truck, a yoke having members supported thereby to have longitudinal movement, means for moving said yoke, arms pivoted to said members and carrying a shovel at their forward ends, quadrants secured to said arms, stationary and movable sheaves, chains secured to said quadrants and passing around said stationary and movable sheaves, the opposite ends of said chains being secured to a fixed part of the frame, and means for moving said movable sheaves to elevate the arms, and buffers on the frame to contact with said quadrants, substantially as described.

10. In combination, a suitable truck, guides supported thereby, a yoke having side members movably supported in said guides, arms pivoted to said members carrying a shovel at their forward ends, a cylinder and piston for operating said yoke, quadrants secured to said arms, a lifting-cylinder having a piston, a cross-head operated by said piston, sheaves carried by said cross-head, a second pair of sheaves journaled on stationary axes, and chains secured to stationary parts of the frame, passing around said sheaves and having their opposite ends passing around the quadrants and secured for lifting the arms, substantially as described.

11. In combination with a suitable truck, arms pivotally supported thereby carrying a shovel at their forward ends, quadrants carried by said truck, a cross-head carrying sheaves operatively connected to said piston, sheaves journaled on stationary axes, and lifting-chains passing around said sheaves and having their ends connected respectively with the arms and a stationary part of the frame, substantially as described.

12. In combination, with a suitable support, arms pivotally supported thereby carrying a shovel at their forward ends, quadrants carried by said arms, chains connected at one end to act on said arms, and passing over said quadrants, the opposite ends of said chains being connected to a fixed part of the support, idler-sheaves over which the intermediate portions of said chains pass, and means for moving said idler-sheaves to strain the chains and elevate the arms, substantially as described.

13. In combination with a suitable truck, arms pivotally supported thereby carrying a shovel at their forward ends, quadrants carried by said arms, chains connected with said quadrants, means for applying tension to said chains to raise the arms, and yielding buffers for limiting the movement of said quadrants, substantially as described.

14. In combination, a suitable truck, a dumping-chute at the rear thereof, a shovel independent of said chute having a reciprocating and vertical swinging movement and supported by said truck, means for advancing and retracting said shovel and for raising the same, said means causing said shovel to advance to be filled and raised and then to move back to dump the contents into the chute at the rear of the truck, substantially as described.

15. In combination, a suitable truck, a turn-table mounted thereon with means for operating it, horizontal guides supported by said turn-table, a power-cylinder disposed longitudinally of said guides, a yoke having parallel members supported in said guides, connections whereby said cylinder operates said yoke, arms pivoted to said members and carrying a shovel at their forward ends, and a lifting-cylinder having connections for lifting said arms, substantially as described.

16. In combination, a suitable truck, a turn-table mounted thereon, shoveling mechanism mounted upon said turn-table, means carried by the

truck below the turn-table for rotating the latter, and laterally-movable bracing-jacks also carried by said truck below the turn-table, substantially as described.

17. The combination with a suitable truck and shoveling mechanism carried thereby, of transversely-arranged hydraulic jacks carried by said truck and means for operating said jacks independently, substantially as described.

18. The combination with a suitable truck and shoveling mechanism carried thereby, of transversely-arranged hydraulic jacks carried by said truck, pumps also carried by said truck for supplying water to said jacks with means for operating said pumps and means for rendering either jack inoperative, substantially as described.

19. The combination with a suitable truck and shoveling mechanism carried thereby, of hydraulic jacks carried by said truck, a water-tank also carried by the truck and connected with the jacks, means for admitting compressed air to the tank to start the jacks, and other means for supplying water under pressure to the jacks to complete their movement, substantially as described.

20. The combination with a suitable truck and shoveling mechanism carried thereby, of hydraulic jacks carried by the truck, a water-tank having pipe connections to the jacks, means for supplying air under pressure to said tank to impart a rapid initial movement to said jacks and water-pumping mechanism for supplying water under pressure directly to said jacks to complete their movement, substantially as described.

21. The combination with a suitable truck and shoveling mechanism carried thereby, of hydraulic jacks carried by said truck, a pair of pumps for supplying water to said jacks with means for operating said pumps, one of said pumps being connected to each jack, and means for rendering either pump inoperative, substantially as described.

22. The combination with a suitable truck, and shoveling mechanism carried thereby, of hydraulic jacks carried by said truck, a pump having a water-driving pipe leading directly to each of said jacks, check-valves in said pipes, and means for raising either of said check-valves at will to maintain any jack out of action, substantially as described.

23. The combination with a suitable truck and shoveling mechanism carried thereby, of hydraulic jacks for said truck, a water-tank having pipe connections to said jacks, means for admitting compressed air to said tank to force an initial supply of water into said jacks, and pumping mechanism having connections for drawing water from said tank and forcing it into said jacks, substantially as described.

24. The combination with a suitable truck, of a plurality of hydraulic bracing-jacks, a water-tank having pipe connections to said jacks, means for admitting air under pressure to said tank to force an initial supply of water into said jacks, a pump for each jack having pipe connections with the water-tank and with its respective jack, means for operating said pumps, and means for rendering any or all of said pumps inoperative, substantially as described.

25. The combination with a suitable truck carrying shoveling device, of an operating-platform carried thereby, a pair of hydraulic jacks carried by said truck, a pump for each jack located beneath the platform with means for operating said pumps, pipe connections from each pump to its respective jack, a check-valve in each of said pipe connections, and shut-off valves on the platform operatively connected with the check valves, substantially as described.

26. The combination with a suitable truck, of a rigid chute at the rear thereof, a single shovel at the front and independent of said chute arranged to lift the material to be excavated, convey it backward and dump it into said chute, arms having a sliding and pivoted connection with the truck and supporting said shovel, and means for operating said arms, substantially as described.

27. The combination with a suitable truck, of a chute carried at the rear thereof, arms having sliding and pivoted connection with said truck, a single shovel carried at the forward ends of said arms, means carried by the truck for reciprocating said arms and raising and lowering them whereby said shovel is filled, raised, retracted and the contents dumped into said chute, an operating-platform at one side of the truck, out of the path of the shovel, and means on the platform for controlling the mechanism for operating the shovel-supporting arms, substantially as described.

28. The combination with a suitable truck, of a chute at the rear thereof, a single shovel at the front arranged to lift the material to be excavated, convey it backward and dump it into the chute, pneumatic cylinders for operating said shovel, an operating-platform located at one side of the truck, and controlling means on said platform for controlling the operation of the cylinders, substantially as described.

699,681. SLIDE-TRANSFORMER. JAMES HANLEY, Boston, Mass. Filed June 14, 1904. Serial No. 64,718. (No model.)

Claim.—1. A trombone having a detachable pliab-transformer at or near the center of the length of the instrument.

2. A trombone provided with a detachable pliab-transformer at or near the center of its length, the said pliab-transformer having a tuning slide.

3. A trombone having a detachable transformer in its cylindrical section *c'* and at or near the center of the length of the instrument, the passage of which is of the bore of the pump of said section.

4. A trombone comprising the bell, a head, a straight section at the end of the bell, a separate section to which the slide is attached, and an interrupted removable section attached to the instrument and connecting the two parts and forming a pliab-transformer, the said pliab-transformer also having attached tuning means.

5. A trombone comprising the bell, a head, a straight section at the end of the bell, a separate section to which the slide is attached, and an interrupted removable section attached to the instrument and connecting the two parts and forming a pliab-transformer, the said pliab-transformer also having attached tuning means.

6. A trombone having a bell provided with a head and a return-section *c'*, the end of which forms a part of a joint, the section *c'* of the transformer carrying the playing-slide, a mouthpiece, the end of which also forms a part of the joint, a handle or brace attached to the bell, and a high or low pliab-transformer attached to the slide or handle and having joints which connect it with the said two parts of the instrument.

7. A trombone having a handle or brace and detachably connected with the bell of the instrument and with the playing sliding section.

8. A trombone comprising three sections or parts, viz: first, the section comprising the bell and the mouthpiece, intermediate bell end; second, the section embracing the playing-slide; third, one or two or more detachable pliab-transformers one of which pliab-transformers combines the bell and slide sections at or near the center of the length of the instrument and either of which pliab-transformers completes the instrument.

9. A trombone having a bell and an intermediate head, the end of which is fitted to receive an end of a detachable pliab-transformer, a section embracing a playing-slide, the end of which is fitted to receive an end of a detachable pliab-transformer and said detachable pliab-transformers having means for attachment to the bell-section and the playing-slide section and connecting the playing-slide section with the bell-section.

10. A trombone having a removable transformer at or near the center of its length and a rest extending from said transformer.

11. A trombone constructed at or near the center of its length to receive a removable pliab-transformer, the said removable pliab-transformer and means in said pliab-transformer for varying the length of its wind-passage.

699,682. BOX-LID AND TAP SUPPORT. GEORGE W. HANFMAN, Kansas City, Mo. Filed Sept. 6, 1904. Serial No. 74,478. (No model.)

Claim.—1. The combination with a box provided with a hinged lid, of a support, comprising a coil arranged within the box near one of its rear corners, and provided with an angle-arm fitting over the contiguous end of the box, and provided with a second or hinge arm projecting upwardly and rearwardly and terminating in a U-shaped portion embracing the contiguous end of the box-lid, substantially as described.

2. The combination with a box provided with a hinged lid, of a support, comprising a coil arranged within the box near one of its rear corners, and provided with an angle-arm fitting over the contiguous end of the box, and provided with a second or hinge arm projecting upwardly and rearwardly and terminating in a U-shaped portion embracing the contiguous end of the box-lid, and provided also with a coil or convolution to support a card in front of and parallel with the face of said lid, substantially as described.

699,683. GAS-HEATED IRON. BENJAMIN E. HAWES, Washington, D. C. Filed Dec. 14, 1904. Serial No. 55,944. (No model.)

Claim.—1. In a gas-heated flat-iron, the combination with a hollow body provided with air-inlet openings near the bottom thereof, and a rectangular opening in its rear wall, of a burner in said body of less size than the opening in the rear wall and provided with a slotted ear, a top plate provided with a slotted ear adapted to register with the ear on the burner, and means for locking the two ears and body together, whereby the top plate is held to the bottom of the body, substantially as described.

2. In a gas-heated flat-iron, the combination with a hollow body provided with air-inlet openings near the bottom thereof, and a rectangular opening in its rear wall, of a burner in said body of less size than the opening in the rear wall and provided with an ear, a top plate provided with an ear adapted to register with the ear on the burner, and means for locking the two ears and body together, whereby the top plate is held to the bottom of the body, substantially as described.

3. In a gas-heated flat-iron, the combination with a hollow body provided with air-inlet openings near the bottom thereof, and a rectangular opening in its rear wall, of a burner in said body of less size than the rectangular opening and provided with a slotted ear adapted to register with the ear on the burner and with the slot in the rear wall of the body, whereby the top plate is held to the body and the burner locked in any adjusted position with relation to the bottom of the body, substantially as described.

4. In a gas-heated flat-iron, the combination with a hollow body provided with air-inlet openings near the bottom thereof, and a rectangular opening in its rear wall, of a burner in said body of less size than said opening and provided with a slotted ear 20, and also with a slotted ear or lateral extension 25, a top plate provided with a slotted ear adapted to register with the ear 20 on the burner, means for locking the ears 10 and 20 to the body, and means for locking the ear or lateral extension to the body, whereby the top plate is held to the body and the burner locked

in any adjusted position with relation to the bottom of the iron, substantially as described.

699,684. INCORPORATION PREVENTIVE. EDWARD HALL, Chicago, Ill. Filed May 17, 1908. Serial No. 14,989. (No specimen.)

Claim.—A metallic composition for preventing incrustation in steam-generating appliances, consisting of zinc, tin, antimony, mercury, and nitrate of silver; the zinc being present in a greater proportion than that of the tin, the proportion of the tin being greater than that of the antimony, the proportion of the antimony being greater than that of the mercury, and the proportion of the nitrate of silver being less than that of any other element.

699,685. CURTAIN-STRETCHER. HARRY E. HOWARD, Chicago, Ill. Filed Dec. 23, 1901. Serial No. 94,553. (No model.)

Claim.—1. In a curtain-stretcher, a bar having an open vertical slot extending longitudinally therethrough, an attaching-pin formed of a single piece of wire bent to form a base portion adapted to snugly fit said slot in the bar, bent to form an upwardly-projecting hump between the point and the base, and bent to form an acute-angled hook, the angle of which is substantially in the same plane as the center of the base portion, substantially in the manner and for the purpose described.

2. In a curtain-stretcher, a stretcher-bar having a narrow vertical slot extending therethrough near one edge, and with an extension on the lower side of said edge and a stretcher-pin having a base fitting said slot, and provided with a head adapted to engage the portion of the bar overhanging said slot, and having a hook portion adapted to engage an extension on the lower side of the edge of the bar, substantially as set forth.

699,686. ENVELOPE-PRINTING PRESS. WILLIAM J. JENNINGS, Woodbury, N. J., assignor, by direct and mesne assignments, to the Steel Machine Company, a Corporation of New Jersey. Filed Apr. 12, 1901. Serial No. 55,461. (No model.)

Claim.—1. In an envelope-printing press, suitable framework for supporting the operating parts, a vertical platen secured to said framework, a vertical form-holder adapted to slide horizontally, guideways formed upon the face of the platen for holding the envelope while receiving the

impression, automatic means for feeding the envelope from a suitable source of supply to said guideways upon the face of the platen, means for releasing the envelope after it has received its impression, and means operated by the sliding motion of the form-holder for automatically taking the type, substantially as described and for the purpose specified.

2. In combination in an envelope-printing machine, a framework adapted to support the operating parts, a power-shaft journaled in said framework, suitable gearing for transmitting motion from said power-shaft to the operating parts of the machine, a vertical platen secured to the framework of the machine, guides secured upon the face of the platen for holding the ends of the envelope while receiving the impression, fingers upon which the lower edge of the envelope is adapted to rest while receiving the impression, means for causing these fingers to spread and allow the envelope to drop after receiving the impression, slide-bars secured in the frame of the machine and extending forward from the same, slides adapted to slide upon said slide-bars, a vertical form-holder secured to said slides and adapted to slide thereon horizontally, means for communicating motion to said slides for the purpose of reciprocating the same, ink-rollers adapted to travel over the face of the form, an ink-plate from which the rollers are adapted to receive their supply, means for causing these rollers to travel from the ink-plate over the form and back again, adjustable upright guides supported by the framework of the machine for holding a supply of envelopes, a pair of constantly-revolving rollers arranged above the platen, slide-bars secured in the framework of the machine and extending rearwardly from the same, slides adapted to slide upon said slide-bars, a connection connecting said slides with the sliding frame which carries the form, blades secured to said slides and adapted to bear against the lower envelope of the pile and adapted to enter between the envelope and the flap thereof, and feed the same between the two rolls when the slides are brought forward, a shield secured in front of the rolls and adapted to deflect the envelope downward within the guides formed on the face of the platen, substantially as described and for the purpose specified.

3. In combination in an envelope-printing press, suitable framework adapted to support the operating parts, a power-shaft journaled in said framework, a train of gears adapted to transmit motion from the power-shaft to the operating parts of the machine, a vertical platen secured to the front of the framework, adjustable guides secured to the face of the platen for holding the ends of the envelope while being printed, two fingers, upon the end of which the two lower corners of the envelope are adapted to rest while receiving the impression, means for causing said fingers to spread at a predetermined time to allow the envelope to drop after it has received the impression, means for automatically feeding the envelope from the source of supply to the face of the platen, horizontal slide-bars secured in the framework upon each side of the machine and extending forward, a framework adapted to slide upon said slide-bars, a vertical form-holder secured in or formed with said framework and adapted to reciprocate thereon, a crank-wheel journaled in the framework of the machine and adapted to be constantly revolved, a pitman, one end of which is pivotally connected to said crank-wheel, a stud extending outward from the sliding framework, a circular block journaled concentrically upon said stud, the other end of the pitman being pivoted upon said circular block concentrically-journaled block, an arm extending downward from said block, a cover-threaded rod pivoted to the lower end of said arm and adapted to slide through a lug carried by the sliding framework, two thumb-nuts threaded upon the cover-threaded rod upon each side of the lug for the purpose of allowing the eccentric block to be turned backward or forward for the purpose of regulating the impression, an ink-plate journaled in suitable bearings carried by the sliding framework, means for rotating said ink-plate a short distance upon each backward-and-forward movement of the sliding framework, bell-crank levers pivoted to the sliding framework upon each side of the machine, an arm pivoted to the end of one member of each bell-crank lever, ink-rollers carried by the lower ends of said arms, springs arranged to exert tension so as to keep the ink-rollers in contact with the form or ink-plate at all times, a link pivotally connected to the upper end of the other member of the bell-crank lever, the other end of said link being pivotally connected to the stationary framework of the machine, substantially as described and for the purpose specified.

4. In combination with a machine of the character described, vertical adjustable guides adapted to hold a stack of envelopes, said envelopes being placed within said guides horizontally with the flap downward, ledges formed upon the lower end of said guides upon which the envelopes rest, two rollers arranged one above the other above the platen, means for constantly revolving said rollers in contact with one another, said rollers covering surrounding one or both of said rollers, slide-bars extending rearwardly from the framework of the machine, slides adapted to slide upon said slide-bars horizontally, suitable means for sliding said slides, spring-blades secured to said slides and adapted to reciprocate thereon, the end of said spring-blades adapted to enter between the envelope and the flap thereof when the slides are caused to travel forward and then remove

the lower envelope from the stack and feed the same between the two rolls, a plunger guided in suitable guides, the lower end of said plunger being beveled rearwardly, a spring adapted to exert pressure downward upon said plunger, a cut-cover adapted to limit the upward movement of said plunger, a curved shield arranged in front of the rolls and adapted to deflect the envelope downward and cause the envelope to assume a vertical position within the guides formed on the face of the platen, substantially as described and for the purpose specified.

5. In combination with a machine of the character described, a suitable framework, a vertical platen secured to said framework, vertical guides secured to the face of the platen upon each side thereof, two fingers arranged in front of the lower edge of the platen, the two slide-bars supported in suitable bearings, one of said fingers being adjustably secured to one slide-bar, and the other finger adjustably secured to the other slide-bar, a shaft journaled in suitable bearings on the framework and extending longitudinally of the machine, an arm secured to the forward end of said shaft, two pins secured in said arm one upon each side of the shaft, notches formed in the ends of the slide-bars in which the said pins are adapted to rest, an arm extending upward from the other end of the longitudinal shaft, a roller pivoted to the upper end of this arm, a circular cam journaled in suitable bearings in the framework of the machine and adapted to be constantly revolved, said cam adapted to operate upon the roller and rock the shaft for the purpose of spreading the fingers and allowing the envelope to drop, and a spring adapted to return the parts to their normal position when allowed to do so by the cam, substantially as described and for the purpose specified.

699,687. INK-REMOVER COMPOSITIONER'S HOLDER OR PRINTER. ROBERT D. KILLAM, Boston, Mass. Filed June 12, 1901. Serial No. 64,767. (No model.)

Claim.—1. In a machine of the character specified, the combination of a mold-box for holding formative material, a lever, a die-board carried by the lever having dies or formers, and means for vertically adjusting the die-board upon the lever without changing its inclination.

2. In a machine of the character specified, the combination of a frame having a support at its top for a mold-box upon which the mold-box may be slid from the front of the machine, adjustable means for centering the bar upon said support, a lever pivoted to the frame of the machine, movable upward automatically and downward by hand, a die-board holder carried by the lever and adjustably attached thereto with one varying its inclination and also having means for permitting the placing and removal of the die-board.

3. The combination in a machine of the character specified of a support for a mold-box, a means for holding dies or formers and moving them vertically by hand and one or more vibrations, also hand-actuated, during the movement of the lever.

4. The combination in a machine of the kind described of a frame, a movable mold-box supported by the frame, a lever pivoted to the frame, moved upward automatically and automatically held in elevated position, an adjustable die-board holder mounted on the lever, and a removable die-board carried by said holder.

5. The combination in a machine of the kind described of a lever having two die arms and a connecting-handle of their two ends, an adjustable holder comprising two bars having means for carrying a die-board,

one of which is mounted upon one of the lever-arms and the other upon the other, and means for adjusting the bars upon the arms.

6. The combination in a machine of the character specified of the lever-arms, the holder-bars mounted thereon and connected therewith by means of slotted connections and coupling bolts and nuts.

7. The combination in a machine of the character described of the lever, its operating-handle, the vibrator moved in one direction by hand and in a reverse direction by a spring, the die-board holders mounted upon the lever, and the die-board.

8. In a machine of the character specified, the combination of a frame, a mold-box for holding formative material supported on the frame, a lever attached at one end to the frame extending over the mold-box and having a clear motion relatively thereto, and a die-board carrying die or formers mounted upon said lever above said mold-box and movable by said lever toward and from said box.

9. In a machine of the character specified, the combination of a frame, a mold-box for holding formative material mounted upon the frame, a lever attached to the frame and extending over the mold-box and having a clear motion relatively thereto, a die-board carrying die or formers mounted upon said lever and movable thereby toward and from said box, and means for automatically moving said lever and said die-board upward automatically, and for holding them removed from the mold-box.

10. In a press of the character specified, the combination of a mold-box holding formative material and dies or formers mounted upon a lever having a clear motion with respect to the box whereby the molds are progressively formed by the dies and released from the dies and displacement of the material upon the parting of the dies from the molds due to motion avoided.

699,688. LUBRICATOR FOR ENGINES. WILLIAM J. LANE and GEORGE LANE, Poughkeepsie, N. Y. Filed Mar. 12, 1901. Serial No. 61,811. (No model.)

Claim.—1. In combination with an engine-frame carrying an air-pump and a water-pump, an inletting oil-pipe for said frame and pumps, valves for said pumps external to said casing, and means interposed between said valves and pumps for connecting said valves and pumps and preventing the escape of oil from the interior of the casing.

2. A casing for a steam-engine frame, comprising a body portion provided with the flanges 52, packing-rings 54, 56, side plates 51, and cover having the flanges 53.

3. In combination with a vehicle-body, a steam-motor device suspended at an angle below the body, a casing for said motor device, and a body of oil carried in said casing.

4. The combination with a motor-vehicle, of a two-cylinder reciprocating engine suspended at an angle below said vehicle-body, a casing including said engine-frame, a body of oil carried in said casing, and means whereby the body of oil and condensed water within the casing cannot rise above a predetermined level.

699,689. FIRE-RESISTING WINDOW. THOMAS LEE, Hono. Oreg. Filed Dec. 28, 1901. Serial No. 57,678. (No model.)

Claim.—1. In a fire-resisting window, the combination of an outer frame provided with ambryes, an upper and lower sliding sash fitted into

these ways and operatively connected to each other so that movement of one cash effects also the other, the lower cash being heavier than the upper one, so as to have a normal tendency to drop and close, thereby raising and closing also the upper cash, a pull-rope to sustain the cashes in an open position against the action of the heavier cash and a suitable connection connected to this pull-rope.

2. In a fire-resisting window, the combination of an outer frame provided with casework, an upper and lower sliding cash fitted into these ways and operatively connected to each other so that movement of one cash effects also the other, the lower cash being heavier than the upper one, so as to have a normal tendency to drop and close, thereby raising and closing also the upper cash, a pull-rope or its equivalent attached to the connected cashes to open them and hold them so, a guide-pulley for this pull device and a support for it, the same being covered within the window-opening in the highest part thereof and of a material susceptible to destruction at a predetermined temperature.

3. In a fire-resisting window, the combination of an outer frame, provided with casework, sliding cash-frames fitted thereto consisting each of four hollow sheet-metal box-frame sections, means to support these cash-frames, rollers carried by them and interposed between their upright members and the casework and springs upon which these rollers are mounted and whereby they are yieldingly held in contact with the casework.

4. In a fire-resisting window, the combination of an outer frame consisting of four sheet-metal box-frame sections, the inner sides and two adjacent ones of the upright sections being integrally connected and formed of one piece, so shaped as to contain the casework, a recess for the parting-strip between them and a cash-guide, the outer side being connected thereto by clamped means and having part of it between its upright edges bent outwardly to form a projecting nose adapted to be engaged by parts of the wall within which this frame is set, thereby holding it in place and cashes fitted to this frame.

5. In a fire-resisting window, the combination of an outer frame, cashes fitted thereto consisting each of four hollow sheet-metal box-frame sections, glass panels obtained by turning the edges of the sheet metal of the cash-frames parallel inwardly thereto and then outwardly again forming flanges and members G closing the bottom of these grooves and being held in place by clamping the flanges mentioned.

699,690. STRUCTURE FOR STORAGE AND DELIVERY OF MERCHANDISE. EDWARD B. LEHRMAN, York, England. Filed July 9, 1901. Serial No. 57,000. (No model.)

Claim.—1. In a structure for the storage and delivery of articles of merchandise a plurality of contiguous compartments having inclined floors, walls for said compartments which alternately approach toward and recede from the median line and form a zigzag path in each compartment and fitting-pieces in the angles of said compartments, substantially as set forth.

2. In a structure for the storage and delivery of articles of merchandise comprising a plurality of contiguous compartments having inclined

floors, a vertically-pivoted wing capable of being folded against the wall of the compartment with which it is used and of being extended into the compartment; a projection from the wing-pivot, a catch connected with the said projection, a longitudinal reciprocable rod having ends thereon adapted to be engaged by the said catches, and means for reciprocating the rod whereby the wing may be positioned to act as a stop or to be folded out of the way, substantially as set forth.

3. In a structure for the storage and delivery of articles of merchandise comprising a plurality of contiguous compartments having inclined floors, an inclined tray common to a series of compartments and having converging sides and an open end, so that articles delivered to the tray from any compartment slide down it and are delivered from the open narrow end, substantially as set forth.

4. In a structure for the storage and delivery of articles of merchandise comprising a plurality of contiguous compartments having inclined floors, a truck having an inclined table thereon with converging sides, adapted to be moved to a series of compartments and to receive goods from them or any of them and to deliver the said goods from its narrow lower end, substantially as set forth.

699,691. STEAM AND OIL SEPARATOR. JOHN T. LINDSTROM, Alhambra, Pa. Filed Nov. 9, 1901. Serial No. 51,728. (No model.)

Claim.—1. A steam and oil separator, comprising a suitable casing, a nest of transversely-arranged bars in the casing laid in vertical series and having spaces between them, the bars of each succeeding layer intersecting the spaces of the layer below, a steam-pipe entering the casing above and discharging below the nest of bars, a steam-box disposed in the upper portion of the casing having inlets in its top, and a steam-outlet pipe leading from the steam-box above the nest of bars.

2. A steam and oil separator, comprising a suitable casing, a nest of transversely-laid bars in the casing placed in vertical series and having spaces between them, the bars of each succeeding layer intersecting the spaces of the layer below, a steam-pipe entering the casing above and discharging below said bars, a steam-box having a perforated cover or top, in the upper portion of the casing, and a steam-outlet pipe leading from the bottom of the steam-box through the wall of the casing.

3. A steam and oil separator, comprising a suitable casing, a nest of transversely-laid bars in the casing, conical in cross-section and placed in vertical series with spaces between them, the bars of each succeeding layer intersecting the spaces of the layer below, a steam-pipe entering the casing above and discharging below the said bars, a steam-box in the upper portion of the casing, having a perforated cover, a steam-outlet pipe leading from the steam-box through the casing, and means in the bottom of the casing to draw off the water of condensation and the oil.

4. A steam and oil separator, comprising a casing, separator arranged therein, a steam-pipe discharging beneath the separator, a steam-box disposed in the casing above the separator and provided with steam-inlets, and a steam-discharge leading from the steam-box out of the casing.

699,692. WRENCH. CHARLES C. LOWMAN, Halifax, Canada. Filed Sept. 21, 1901. Serial No. 70,004. (No model.)

Claim.—1. A pipe-wrench comprising a handle toothed at one edge, a pipe-engaging member at one end of said handle, a slide mounted on the handle, a detent pivotally connected to the extended portion of the slide and extending forwardly therefrom, and having the side of its forward portion adjacent to the toothed edge of the handle toothed and also having a hook on said forward portion, and a second pipe-engaging member suitably connected with the handle and having a connection removably engaged with the hook of the detent on the slide.

ing a connection adapted to be placed in engagement with the hook of the detent on the slide.

2. A pipe-wrench comprising a handle toothed at one edge, a pipe-engaging member at one end of said handle, a slide mounted on the handle and extended beyond the toothed edge thereof, and having the transverse portion arranged to engage the edge of the handle opposite to the toothed edge, a detent pivotally connected to the extended portion of the slide and extending forwardly therefrom, and having the side of its forward portion adjacent to the toothed edge of the handle toothed and also having a hook on said forward portion, and a second pipe-engaging member suitably connected with the handle and having a connection removably engaged with the hook of the detent on the slide.

3. A pipe-wrench comprising a handle toothed at one edge, a pipe-engaging member pivotally connected to one end of said handle, a slide mounted on the handle and extended beyond the toothed edge thereof, and having the transverse portion arranged to engage the edge of the handle opposite to the toothed edge, a detent pivotally connected to the extended portion of the slide and extending forwardly therefrom and having the side of its forward portion adjacent to the toothed edge of the handle toothed and also having a hook on said forward portion, and a chain consisting of a second pipe-engaging member, connected at one end to the first-named pipe-engaging member, and provided at its opposite end with a connection adapted to be placed in engagement with and disengaged from the hook of the detent on the slide.

4. A pipe-wrench comprising a handle toothed at one edge, and having its forward and reduced, links pivotally connected to said reduced end and having portions arranged to abut against shoulders of the handle, and also having notches in their forward edges, a toothed dog seated in said notches of the links and having a shank extending between the links, means for securing the shank in the links, a slide mounted on the handle, a hook pivotally connected to the slide and having a toothed edge or side arranged to engage that of the handle, and a chain connected to the links on the handle, and having a connection adapted to be engaged with the hook on the slide.

5. In a pipe-wrench, the combination of parallel links having notches in their edges, a toothed dog seated in said notches and having a shank extending between the links, and means at the back of the links engaging the shank and covering the dog in its seat in the links.

699,693. PIPE-WRENCH. CHARLES C. LOWMAN, Halifax, Canada. Filed Sept. 21, 1901. Serial No. 70,004. (No model.)

Claim.—1. In a pipe-wrench, the combination of a handle toothed at one edge and having a pipe-engaging member or jaw at its end, forward and rear slides mounted on the handle, a second pipe-engaging member pivotally connected at the rear end of its shank to the forward slide, a link pivotally connected to said shank and the forward slide, and extending rearwardly therefrom, and a hook engaged with the link and

pivotally connected to the rear slide and having its edge or side adjacent to the toothed edge of the handle correspondingly toothed.

2. In a pipe-wrench, the combination of a handle toothed at one edge, a head at the end of the handle having the convex inclined face, and the groove therein, a gripper having a reduced portion curved and adapted to move in the groove of the head, and also having shoulders curved and inclined in conformity to the face of the head, a slide mounted on the handle and extended beyond the toothed edge thereof, and having the transverse portion arranged to engage the edge of the handle opposite to the toothed edge, a link pivotally connected to the extended portion of the slide and extending forwardly therefrom, and having the side of its forward portion adjacent to the toothed edge of the handle toothed, a jaw having a shank disposed at the side of the handle, a slide straddling the handle and connected to said shank, and a connection between the shank and the pivoted and toothed link.

699,694. HAND-ROLLER. CHARLES K. LOWMAN, Brooklyn, N. Y., assignor of one-half to Julian Schell, New York, N. Y. Filed Sept. 7, 1901. Serial No. 74,000. (No model.)

Claim.—1. A hand-roller having a cylindrical face, a pair of heads and hollow annular flanges uniting the face with the heads, said flanges projecting laterally outward beyond the heads and curving inwardly to the face of the roller.

2. A hand-roller comprising a cylindrical face, a pair of heads, and hollow annular flanges uniting the face with the heads, said flanges projecting laterally outward beyond the heads and curving inwardly to the face of the roller, and having internal ribs arranged to brace the flanges radially.

3. A hand-roller comprising a cylindrical face-plate, and a pair of heads secured thereto by hollow flanges, said flanges extending laterally outward from the heads and curving inwardly to the face-plate and being united to said plate by a flush joint.

4. A hand-roller comprising a cylindrical face-plate and a pair of heads secured thereto by radially-braced hollow flanges, said flanges extending laterally outward from the heads and curving inwardly to the face-plate and being united to the face-plate by a flush joint.

5. A hand-roller comprising a cylindrical face-plate, a pair of heads

and separate hollow flanges secured to the heads and face-plate, said flanges projecting laterally outward beyond the heads and curving inwardly to the face-plate, and being secured to said plate by a flush joint.

6. A lead-roller comprising a cylindrical face-plate, a pair of heads and separate hollow flanges secured to the heads and face-plate, said flanges projecting laterally outward beyond the heads and curving inwardly to the face-plate and making a flush joint therewith, and said flanges having internal ribs arranged to brace them radially.

699,695. SNAP-HOOK. BYRON P. MATTHEW, Walton, Iowa. Filed Oct. 18, 1900. Serial No. 33,377. (No model.)

Claim.—A snap-hook comprising the loop 5 continuing to form the recurve hook 1, said hook extending in a plane at right angles to a plane passing through said loop, the cutting 6 provided within the hook and 1, upon the under side, a depression upon the side between the loop 5 and hook 1, the pin 3 passing through said hook 1, within said depression, the sheet-metal tongue 2, secured to said pin 3, the loop 7, secured to said sheet-metal tongue 2, and the spring 4 held within said loop 7, winding about said pin 3, and being secured to said hook near the loop and 5, all arranged substantially as, and for the purpose set forth.

699,696. WINDOW-FARTHER. GEORGE R. MEALIN, Chicago, Ill. Filed Dec. 24, 1901. Serial No. 37,003. (No model.)

Claim.—1. A locking device of the class described, in which is combined a case adapted to be secured to one of the members to be locked, an elbow-shaped locking-dog, pivotally secured therein, a rack upon the counterpart member to be locked, said rack being in position to be engaged by the teeth upon one arm of said locking-dog, a sliding spring-actuated follower-block arranged to wedge beneath the heel of said locking-dog, a horizontal slot having a notch in the upper side of its rear end and a pin or knob upon said follower-block, said pin being projected through said slot and fitted to engage said notch when in an abnormal position.

2. A window-frame in which is combined a rack attached to the vertical rail of the upper sash, a lock-case attached to the top of the vertical rail of the lower sash, an elbow-shaped locking-dog pivotally mounted within said case and in position to engage said rack, the heel of said locking-dog being heavier than the engaging arm thereof, a spring-actuated follower-block arranged to slide beneath said heel and means for securing said follower-block in an abnormal position.

3. In a window-further, the combination of a rack attached to the vertical rail of the upper sash, a lock-case attached to the top of the vertical rail of the lower sash, an elbow-shaped locking-dog pivotally mounted within said case in position to engage said rack, the heel of said locking-dog being heavier than the engaging arm thereof, a spring-actuated follower-block arranged to slide beneath the heel of said locking-dog, a pin attached to said follower-block and extending laterally through slots in the case and sash upon the ends of said pin whereby said block may be automatically locked against a backward movement.

4. In a window-further, the combination of a pivoted locking-dog arranged to be moved into an abnormal or unlatched position by the action of gravity, a spring-actuated follower-block for pushing and wedging said dog into a locked position and gravity friction-cams for normally holding said follower-block against a backward movement.

699,697. CARTON. HENRI L. HENRIOT, Salt Lake, Mexico. Filed Aug. 31, 1901. Serial No. 74,067. (No model.)

Claim.—1. The combination with a pan, of a canteen adapted to rest therein, a raised portion upon one face of the canteen, and a cover for the pan adapted to fit upon said raised portion.

2. The combination with a pan, of a canteen adapted to rest therein, a raised portion upon one face of the canteen, a cover for the pan adapted to fit upon said raised portion, a bottom upon the cover and upon the canteen, and a strap adapted to extend around the pan and canteen and engage the bottom.

3. The combination with a canteen having a raised portion upon one face; of a series of pans of different sizes adapted to rest one within the other, flanges, angular in section, at the edges of the pans, the flange of one pan being adapted to receive the bottom of the next largest, a lid or cover for the pans adapted to fit upon the raised portion of the canteen, and means for securing the canteen and nested pans, together.

4. A device of the character described comprising a series of pans of different sizes adapted to rest one within the other, angular flanges at the edges of the pans, the flange of one pan being adapted to receive the bottom of the next largest pan, a canteen adapted to rest within the nested pans, a raised portion upon one face of the canteen, a lid adapted to fit either upon said raised portion or upon a pan, a strap for securing the pans and canteen together, and a carrying-strap extending under the pans.

699,698. SEPARABLE SCREEN-HINGE. HERMAN W. MURRAY, Milton, Mass. Filed Aug. 7, 1901. Serial No. 71,347. (No model.)

Claim.—1. A separable hinge comprising a portion adapted to be permanently secured to a stationary part, and a portion adapted to be secured to a movable part, the latter portion comprising a plate to be secured to said movable part, and a plate pivoted thereon, said pivoted plate and said permanent portion having interlocking lugs and apertures to receive said lugs, said lugs filling said apertures, said lugs having overhanging portions of projecting toward each other, and means for engaging beneath said lugs against the plates having the apertures for holding the separable parts of the hinge together.

2. A separable hinge comprising two plates pivoted together and a spring for yieldingly holding said plates apart, one of said plates having means for securing it to a door, and the other of said plates having opposite apertures, combined with a detachable plate provided with lugs adapted to fit said apertures, said lugs having overhanging portions for

projecting through said apertures, and said spring having projecting ends adapted to rest beneath said overhanging portions for locking the two parts together.

699,699. MEASURED-FEED APPARATUS. SPENCER E. FOWLER, Sandusky, Ohio, assignor to the Sandusky Portland Cement Company, Sandusky, Ohio, a Corporation of West Virginia. Filed Feb. 4, 1901. Serial No. 33,511. (No model.)

Claim.—1. In a measured-feed apparatus, the combination of a rotatable disk, a plurality of impervious buckets removably carried on one side of said disk and capable of angular adjustment thereon whereby the capacity is regulated, a tub into which said buckets dip in the lower portion of their travel, a hopper within the tub into which said buckets discharge in the upper portion of their travel, and an overflow-pipe for preserving a constant level in the tub, substantially as described.

2. In a measured-feed apparatus, in combination, a metal tub, a hopper formed by a metal plate pivoted to the inner side thereof, a rotatable disk extending into said tub, a shaft carrying said disk, a plurality of removable impervious buckets secured to said disk by arms passing through openings in the disk, an admission-pipe and an overflow-pipe for said tub, substantially as described.

699,700. FLAT-IRON HEATER. WILLIAM F. FENIGAN, Chicago, Ill. Filed Jan. 20, 1901. Serial No. 33,439. (No model.)

Claim.—1. In a gas-stove the combination, with a burner, a housing provided with a plurality of inclined sides, an angular trunk on the base of said housing, a base and a series of rollers supported thereon adapted to engage said trunk, whereby said housing may be rotated.

2. In a gas-stove the combination, with a burner, a housing provided with a plurality of inclined sides, an angular trunk on the base of said housing, a base, a series of rollers supported thereon, adapted to engage said trunk, a lid adapted to cover the top of said housing, and a flame-spreader depending from said lid and immediately over said burner.

699,701. RATCHET-DRILL STOCK AND SUREW-DRIVER. HENRY HOBBS, Cambridgeport, Mass. Filed Feb. 12, 1900. Serial No. 33,304. (No model.)

Claim.—The herein-described ratchet-drill stock, consisting in combination a tongue or handle H, a ratchet extension G, G', attached to or made integral with the part H, a blade D, secured to said ratchet extension, a pair of plates F, F', secured to the blade D, a cogwheel I journaled on said plates and having secured to it a ratchet-wheel L, and provided with a fixed-curve Q, a pivot-carrier K pivoted to said plates and provided with parts E and N, adapted to be swung into engagement with the ratchet-wheel I and provided with a spring M, for holding either of said parts in engagement with the ratchet-wheel I, substantially as and for the purpose set forth.

699,701.

699,702. KITCHEN-CABINET. JOHN P. FALAMINE, Fredericks, Wis. Filed Jan. 4, 1902. Serial No. 34,433. (No model.)

Claim.—1. In a kitchen-cabinet, a compartment, a bank of pipes located within the compartment and connected in alternation at opposite ends, the end pipes of the series extending through opposite ends or walls of the cabinet, and a vertical pipe connected centrally with the lowermost pipe of the horizontal series for supplying either hot or cold air thereto, substantially as set forth.

2. In a kitchen-cabinet, a compartment having an opening in its bottom, a series of horizontal pipes located within the structure and connected in alternation at opposite ends, the end pipes of the series extending through opposite walls of the cabinet, a vertical pipe connected with the lowermost pipe of the horizontal series at a point mid-way of its ends, and a second pipe surrounding the said vertical pipe and in line with the opening in the bottom of the cabinet and adapted to supply fresh air thereto, substantially as set forth.

3. The herein-described kitchen-cabinet comprising a compartment or box-like structure mounted upon legs and having an opening in its bottom, a central support within the compartment, upper and lower grates, a series of horizontal pipes located in the rear of the compartment and connected at opposite ends in alternation, the end pipes of the series extending through opposite ends of the compartment, a vertical pipe connected with the lowermost horizontal pipe and extending through the bottom of the compartment and adapted to receive the upper portion of a lamp-chimney, and a second pipe surrounding the vertical pipe and in line with the opening in the bottom of the compartment and terminating

about in the plane of the top side thereof, substantially as and for the purpose set forth.

699,708. MAGAZINE-FIREARM. SAMUEL PARSONS, Kansas City, Mo. Filed Dec. 12, 1891. Serial No. 65,893. (No model.)

Claim.—1. In a firearm, a compound magazine mounted rotatably below the barrel, two sets of pointed projections secured on the magazine, said projections in one set being pointed toward the projections in the other set, and the number of said projections in each set corresponding to the number of barrels or tubes in the magazine, an action-slide comprising a sleeve embracing the portion of the magazine having said projections thereon, said sleeve being movable longitudinally on the magazine but not rotatable, two sets of pointed projections secured within said sleeve, the projections in said sets pointing oppositely, and lying between the abutting pointed projections on the magazine, the projections in said sleeve being so arranged that when said sleeve is moved in one direction over the magazine, one set of projections in said sleeve will engage the corresponding set of projections on the magazine, and will thereby partially rotate the magazine, and when said sleeve is moved in the opposite direction over the magazine, the other set of projections in said sleeve will engage the other set of projections on the magazine, and will thereby further rotate the magazine; substantially as and for the purpose described.

2. In a firearm, an action-slide having a rearward extension, a block secured to said action-slide, a notch 51 in the upper face of said block, a hammer having a cam portion 36', a slide-lock consisting of a forwardly-extending catch mounted pivotally below the hammer, said catch being adapted to engage said notch in said block and an extension of said catch arranged to be depressed by said cam portion of the hammer when the hammer is closed, thereby holding said catch disengaged from said notch to permit said action-slide to be moved forward; substantially as described.

3. In a firearm, an action-slide having a rearward extension, a block secured to said action-slide, said block having an inclined rear face, a notch 51 in the upper face of said block, a hammer having a cam portion 36', a slide-and-hammer lock comprising a forwardly-extending catch and a rearwardly-extending portion having a heel or detent 48 thereon, a notch 47 in the rear face of said cam portion of the hammer, a pivot-pin extending through said slide-and-hammer lock between said catch and said rearwardly-extending portion; the action of said parts being that when said slide and block are moved back, the inclined rear face of said block will raise said catch and thereby disengage said detent 48 from said notch 47, thereby permitting the hammer to fall when released by the trigger; substantially as described.

4. In a magazine-firearm, the combination, with the receiver, of an action-slide having a rearward extension, a block secured thereto, said block having an inclined front face, a cartridge-opening 10 in the front wall of the receiver, a carrier having a cartridge-pocket 29 and an inclined lower face 29, a lever, a link connecting the lower end of said le-

ver to said block, said lever lying partly between the arms of said carrier, and pins projecting from the upper end of said lever, whereby the forward motion of said block raises said carrier to register with the bore of the barrel, while the backward motion of said block moves the upper end of said lever obliquely downwardly, causing said pins to follow the arms of said carrier down until the cartridge-pocket in the receiver registers with said cartridge-opening in the front wall of the receiver; substantially as described.

5. In a magazine-firearm, an action-slide having a rearward extension, a block secured to said extension, a link pivotally connected to said block, a breech-bolt provided with depending legs, arranged to form a vertical slot therebetween, and a lever having its upper end extending into said slot and its other end pivotally connected to said link, whereby movement of said slide in either direction will move said breech-bolt in the opposite direction, substantially as described.

699,704. VALVE-OPERATING MECHANISM FOR WARE-HOUSES. EDGAR R. PARSONS, Moorhead, Iowa. Filed Nov. 9, 1901. Serial No. 61,732. (No model.)

Claim.—1. The combination with a basin provided with an outlet orifice, of a valve seated therein; a valve-stem projecting from said valve; a removable plate provided with an upturned lip at one end; a lever fulcrumed at the other end of the plate and adapted to rest on the lip; an eye formed intermediate the lever and adapted to engage the stem of the valve whereby the same may be actuated to close or open the outlet-orifice.

2. A stopper mechanism for basins comprising a plate having upwardly-projecting legs or ears on one end; a lever fulcrumed to said ears consisting of a single piece of wire bent to engage the fulcrum; thence bent to form an eye intermediate the ends of said lever and terminating in a handle; of a valve-stem connected to the intermediate eye of the lever; and a valve on the other end of said valve-stem.

699,705. WAGON-GEAR. GEORGE H. PERRY, Franklin, Tenn. Filed Aug. 2, 1901. Serial No. 71,362. (No model.)

Claim.—The combination with a running-gear, of a double-throw composed of a centrally-pivoted central section extending from opposite sides of the tongue, and the independently-movable and stationary pivots connected to the ends of the central section and capable of moving backward and forward simultaneously to permit both horses to move backward and forward simultaneously to points to advance and in rear of the pivot point of the central section in pulling and backing, and the stay-chains

connecting the end sections of the double-throw with the running-gear and provided with cushioning-springs and adapted to permit such independent movement of the said end sections, substantially as described.

699,706. FAN. CHARLES B. FISKE, Cleveland, Ohio. Filed July 14, 1901. Serial No. 62,600. (No model.)

Claim.—1. A folding fan comprising a series of sections comprising ribs and web-sections, the ribs expanding when the fan is opened in one direction and two of the ribs of each two sections coming together and held in place by opposite folds of the web-sections therebetween when the fan is opened in an opposite direction to produce a continuous web, substantially as set forth.

2. In a folding fan comprising two sets of ribs, even and odd alternately arranged and web-sections, the latter being attached to the even and reverse sides of even and odd ribs in successive order, whereby when the fan is opened in one direction the sections will separate and when opened in the opposite direction a continuous web will be produced, substantially as set forth.

699,707. RIVETING-MACHINE. HENRY C. FENNERTY, Chicago, Ill. Filed Oct. 26, 1900. Serial No. 34,981. (No model.)

Claim.—1. In a riveting-machine, the combination with a slidable die, of a device mounted above the die having independent means for moving the same in one direction successive distances relative to different lengths of rivets, and a plunger having a fixed length of travel and adapted to cooperate with said die; substantially as specified.

2. In a riveting-machine, the combination with a movable die, of a device mounted above the die for moving the same in one direction and having a series of contact-faces at different distances from a fixed point relative to different lengths of rivets, a plunger adapted to cooperate with said die and having a fixed length of travel, means for retracting said die in the reverse movement of the advancing device, and means for retracting said plunger and its operating-lever when pressure is relieved from the same; substantially as specified.

3. In a riveting-machine, the combination with a casing or housing, of a movable die, an adjustable device adapted to contact with said die having a series of faces disposed at different distances from a pivotal point relative to different lengths of rivets and adapted to be successively brought into contact with said die, and a movable plunger cooperating with said die; substantially as specified.

4. In a riveting-machine, the combination with a casing or housing, of a movable die, an adjustable device adapted to contact with said die having a series of faces disposed at different distances from a pivotal point relative to different lengths of rivets and adapted to be successively brought into contact with said die, a movable plunger cooperating with said die, a spring for retracting said die, a spring for retracting said plunger, an operating-lever pivoted in said casing and having a projection adapted to engage and move said plunger; substantially as specified.

5. A casing for a riveting-machine having a horizontally-disposed base portion, a casing disposed at the forward end of said base, an operating face at the upper portion of said casing, a neck provided with pivoting-ears and extended over said operating face, a stop-rib disposed at one side of said neck, a rearwardly-extending base portion, and a rib deflecting laterally from the center of said neck to one side of said base; substantially as specified.

6. In a riveting-machine, a casing or housing provided with a casing at its forward portion and pivoting-ears above said casing, an adjustable die slidably mounted between said ears, a cam device pivoted at the upper portion of said ears and provided with a series of faces at different distances from the pivot, relative to different lengths of rivets, a spring for retracting said die, and a plunger for cooperating with said die; substantially as specified.

7. In a riveting-machine, a casing or housing provided with a casing at its forward portion and pivoting-ears above said casing, an adjustable die slidably mounted between said ears, a cam device pivoted at the upper portion of said ears and provided with a series of faces spaced from said pivot at distances relative to different lengths of rivets, a spring for retracting said die, a plunger slidably mounted at the upper portion of said casing, a spring for retracting said plunger, an operating-lever pivoted to said casing and provided with a projection lying beneath said plunger; substantially as specified.

8. In a riveting-machine, the combination with a movable die, of a pivoted cam device having a series of flat faces spaced from the pivot at distances relative to different lengths of rivets adapted to bear against a portion of said die to advance the same to different degrees, and a plunger having a fixed length of travel; substantially as specified.

9. In a riveting-machine, the combination with a casing or housing provided at its forward portion with a casing and a neck having pivoting ears or legs, of a die slidably mounted between said ears and having a transverse head, a retracting-spring disposed between said head and casing, an adjusting-cam device pivoted above said die and having a series of flat faces spaced from the pivot at distances relative to different lengths of rivets, a plunger slidably mounted in said casing beneath said die, a laterally-extending head to said plunger, a spring disposed between said head and casing, and an operating-lever pivoted to said casing and provided with an arm beneath said plunger; substantially as specified.

10. In a riveting-machine, the combination with a casing or housing provided at its forward portion with a casing and a neck having pivoting ears or legs, of a die slidably mounted between said ears and having a transverse head, a retracting-spring disposed between said head and casing, an adjusting-cam device pivoted to said ears above said die and having a series of flat faces spaced from the pivot at distances relative to different lengths of rivets, a plunger slidably mounted in said casing beneath said die, a laterally-extending head to said plunger, a spring disposed between said head and casing, an operating-lever pivoted to said casing and provided with an arm beneath said plunger, a stop-rib extending from the casing above the outer end of said plunger-lever, a cover-plate for said casing, a bolt for said operating-lever passing through the casing, lever and cover-plate, and a projecting arm at the base of said casing lying beneath the extended free end of the plunger-operating lever, substantially as specified.

699,708. TOOL-HOLDER. CHARLES F. FENNERTY, Chicago, Ill. Filed July 26, 1901. Serial No. 62,704. (No model.)

Claim.—1. A tool-holder, comprising a casing, a slide movable in said casing and adapted to project at its forward end therefrom, the said forward end of the slide being retained and forced with a beveled top for engaging the tool and pressing the same against a correspondingly-beveled wall of the casing, as set forth.

2. A tool-holder, comprising a casing, and a slide having a rectangular body portion fitted in the opening of the casing, the forward end of said slide being retained and the top of said retained portion being beveled inward and downward, opposite a corresponding level in the top wall of the casing, the said retained end of the slide being adapted to be moved into an outermost position to permit of the insertion of a tool between said beveled surfaces, as set forth.

3. A tool-holder, comprising a casing, a slide movable in the casing, one face of said slide at one end being beveled inward opposite a corresponding level in the wall of the casing, and a set-screw extending through the wall of the casing and engaging the slide.

4. A tool-holder, comprising a casing, a slide movable therein, the slide having one end retained, the top of the retained portion being beveled inward and downward opposite a corresponding level in the top wall of the casing, and a set-screw engaging in the casing against the

bevel on the side, to lock the latter in place after adjustment is made, as set forth.

699,709. ELASTIC SUPPORT FOR VEHICLE. ARTHUR F. MANN, London, England. Filed Dec. 3, 1903. Serial No. 94,497. (No model.)

Claim.—1. In a vehicle, the combination with a supporting axle, of a box-shaped frame carried thereby, a body extending within said frame, cushioning devices located between the vertical walls of the frame and the vertical walls of the body, and independent cushioning devices between horizontal portions of the frame and horizontal portions of the body, substantially as described.

2. In a vehicle, the combination with the axle, of a suitable frame including vertical side members, a body having a portion depending within said side members, cushion devices beneath said body for yieldingly supporting the same, and independent cushion devices between said side members and the depending side portions of the body, substantially as described.

3. In a vehicle the combination with the supporting axle, of a suitable frame secured thereto, having vertical side walls or portions, a body having a portion seated within said side walls, cushion devices interposed between said frame and body, cushion devices interposed between said body and said side walls, a platform beneath the axle, connections between said platform and the body, and cushion devices between said platform and the frame, substantially as described.

4. In a vehicle, the combination with the supporting axle, of a suitable frame secured thereto, having vertical side walls or portions, a body having a reduced portion depending within said side walls, cushion devices interposed between the bottom of said reduced portion and said frame, a platform beneath the axle connections between said platform and body, and cushion devices between said platform and the frame, substantially as described.

5. In a vehicle, the combination with the supporting axle, of a suitable frame secured thereto, a body having a reduced portion or bottom located in proximity to said frame, a platform located beneath the axle and frame, cushion devices located between said reduced body-bottom and frame and between the frame and platform, and tie-rods connecting the enlarged portions of the body with the platform, substantially as described.

6. In a vehicle, the combination with the supporting axle, of a suitable frame secured thereto, a body having a reduced portion or bottom located in proximity to said frame, a platform located beneath the axle and frame, cushion devices located between said reduced body-bottom and frame and platform and frame, and tie-rods connecting the enlarged portions of the body with the platform, said tie-rods having universal joint connections with the body and platform, substantially as described.

7. In a vehicle, the combination with the supporting axle, of a frame carried thereby, an elongated pneumatic cushion seated on said frame, a body having its bottom supported on said cushion, a platform beneath the axle, tie-rods connecting the platform with the body, and an elongated pneumatic cushion interposed between the frame and platform substantially as described.

8. In a vehicle the combination with the supporting axle, of a box-shaped frame carried thereby having vertical side walls, of a body having a portion depending within said side walls, an elongated pneumatic cushion between the bottom of the body and the frame, and independent pneumatic cushions between the sides of said body and the vertical walls of the frame, substantially as described.

699,710. CORE-MOLDING MACHINE. JAMES H. FROST, JR., Chicago, Ill. Filed Jan. 11, 1909. Serial No. 95,399. (No model.)

Claim.—1. A core-molding machine, comprising a frame, a tube secured in said frame and open at its ends, a rod extending longitudinally within said tube, means for supplying core material to said tube, and a plunger longitudinally slidable within said tube and along said rod and

adapted to force said material through said tube, said plunger having its forward end inclined so as to force said material upwardly and thereby prevent the formation of cavities in the upper part of the core.

2. A core-molding machine, comprising a frame, a tube secured to said frame and open at its ends, a rod extending longitudinally within said tube, means for supplying core material to said tube, and a plunger longitudinally slidable within said tube and along said rod and adapted to force said material through said tube, said plunger having an aperture extending longitudinally through same and adapted to receive said rod, and having a second aperture separated from the other and adapted to permit the passage of a stiffening wire through said plunger longitudinally of the core.

3. In a core-molding machine, the combination of a frame, a tube secured to said frame, a hollow shaft slidably mounted in said frame in alignment with said tube, a plunger secured to said shaft, forcing said tube and longitudinally slidable therein, a rod secured to said frame and extending longitudinally through said shaft and plunger and into said tube a considerable distance beyond said plunger, means for supplying core material to said tube, and means for causing said shaft to reciprocate longitudinally of said tube and force said material through same.

699,711. FIRE-HOOK. JAMES H. FROST, JR., Chicago, Ill. Filed Mar. 10, 1909. Serial No. 97,512. (No model.)

Claim.—1. In a device of the class described, the combination of three hooks secured together at the shanks thereof, the planes of said hooks being approximately equidistant, and the points of said hooks projecting inwardly and lying approximately in the axial line of the device.

2. In a device of the class described, the combination of three hooks lying in approximately equidistant planes with the points of said hooks projecting inwardly; and means for securing said hooks together at different lengths, the head of one hook lying nearer the common joint than the point of the next longer hook.

3. In a device of the class described, the combination of hooks joined at the upper ends of their shanks and having their points projecting inwardly; and a guard secured to the shanks of the hooks near the joint thereof, said guard being trained toward the points of said hooks for preventing access of weeds thereto.

4. In a device of the class described, the combination of hooks joined at the upper ends of their shanks and having their points projecting in-

wardly; a guard secured to the shanks of said hooks; and a support for supplementing the stiffness of said guard to maintain the same distended.

5. In a device of the class described, the combination of hooks joined at the upper ends of their shanks and having their points projecting inwardly; a guard of fibrous material fastened to the shanks of said hooks near the joint thereof and trained toward the points of the hooks; and a flexible core secured to and extending the shanks of said hooks, said core lying beneath said guard to support the same.

6. In a device of the class described, the combination of three hooks joined together at the shanks thereof, the planes of said hooks being approximately equidistant and the points of said hooks lying approximately on the axis of the device, and said hooks being of different lengths, the head of any one of said hooks lying nearer the upper end of the device than the point of the next longer hook; a guard secured to the shanks of said hooks and extending toward the points thereof; and a collapsible support beneath said guard for normally maintaining the same in a distended condition.

699,712. OVEN. FRANK RABENHAGEN, Los Angeles, Cal. Filed Nov. 15, 1901. Serial No. 62,771. (No model.)

Claim.—1. An oven having a heat refractory fire-chamber inside the oven-chamber furnished with passages opening directly from the tunnel into the oven; a burner for producing fire at one end of the tunnel, an air-inlet being provided below said burner; means for controlling the burner; a chimney; a flue opening from the fire-chamber at the end opposite the burner and leading to the chimney; means for controlling the passage through said flue; and means for forcing a draft through said chimney; said oven being provided with draft-opening; whereby the oven can be alternately heated and cooled.

2. An oven provided with a perforated tunnel, means for supplying heat to the tunnel, and means communicating with the tunnel for drawing air therethrough to cool the same.

3. A ventilated oven provided with a perforated tunnel, an oil-burner at one end of the tunnel, and means communicating with the other end of the tunnel for drawing air therethrough to ventilate the same.

699,713. PLASTIC COMPOUND AND THE METHOD OF MANUFACTURING SAME. LEONARD E. RABENHAGEN, NEWARK, N. J., assignor of three-fifths to LEONARD E. RABENHAGEN and LEONARD E. RABENHAGEN, NEW YORK, N. Y. Filed Sept. 8, 1907. Serial No. 71,446. (No model.)

Claim.—1. The plastic compound herein described, consisting of varnish, rosin, put and oil, substantially as set forth.

2. The plastic compound herein described, consisting of varnish, rosin, put and oil, and a coloring-matter of the desired shade and quantity, substantially as set forth.

3. The plastic compound herein described, consisting of substantially equal parts of varnish, rosin and put and from ten to twenty per cent. of oil, substantially as set forth.

4. The plastic compound herein described, consisting of substantially equal parts of varnish, rosin and put and from ten to twenty per cent. of oil, and a coloring-matter of the desired shade and quantity, substantially as set forth.

5. The method of manufacturing the plastic compound herein specified, consisting in taking equal parts of varnish, rosin and put, thoroughly mixing the same and allowing the material to dry, breaking up the compound and then heating the same until hot, adding thereto in the hot condition from ten to twenty per cent. of oil, and thoroughly incorporating the same with the other ingredients, placing said material in an oven or suitable heater, drying the same, breaking up and grinding the said material into a fine consistency to prepare the same for molding into the desired form, substantially as set forth.

6. The method of manufacturing the plastic compound herein specified, consisting in taking equal parts of varnish, rosin and put, thoroughly

mixing the same and allowing the material to dry, breaking up the compound and then heating the same until hot, adding thereto in the hot condition from ten to twenty per cent. of oil, and a coloring-matter of the desired shade and quantity, and thoroughly incorporating the same with the other ingredients, placing said material in an oven or suitable heater, drying the same, breaking up and grinding the said material into a fine consistency to prepare the same for molding into the desired form, substantially as set forth.

699,714. HEADLIGHT FOR MOTOR-CARS. CHRISTIAN REINER, Cleveland, Ohio. Filed Feb. 11, 1901. Serial No. 63,969. (No model.)

Claim.—1. In motor-car, an arc-lamp having magnet-controlling mechanism, in combination with electrical circuits for said lamp having trolley-wire and trolley-pole connections for conveying the current, and non-conducting sections on said trolley-wire to automatically cut off the current-supply and thereby operate said magnet-controlling mechanism, substantially as described.

2. A headlight for cars having an arc-lamp with magnet-controlling mechanism, in combination with a series of inductance lamps for lighting the car, trolley-wire and trolley-pole with circuits leading to said inductance lamps and arc-lamps, and non-conducting sections on the trolley line-wire to cut off the current at intervals whereby said arc-light-controlling mechanism is actuated, substantially as described.

3. A headlight for cars having both an arc-lamp and an inductance lamp, in combination with electrical circuits for said lamps having trolley-wire and trolley-pole connections for conveying the current, and non-conducting sections on said trolley-wire to cut off the current-supply at intervals, substantially as described.

4. In motor-car, the combination of a trolley-wire, trolley-pole, and non-conducting sections on said wire to break the flow of current, with a headlight having a series of arc-lighting lamps, and means to switch either of said arc-lighting lamps into said circuit, substantially as described.

5. In arc-lamps, a supporting-bracket for both carbons, a magnet and an armature controlled thereby and a shroud pivoted on one end of said armature and a post in which the shroud slides, and a spring arranged to pull the armature away from the magnet, substantially as described.

699,715. DISPLAY DEVICE FOR BOOKS. HENRY BROWN, Chicago, Ill. Filed Mar. 3, 1909. Serial No. 97,392. (No model.)

Claim.—The combination in a display device for books of a plurality of hollow polygonal posts, each of said posts being formed from a single flat sheet-metal blank, the base of the posts being bent on longitudinal lines of the blank and having base portions corresponding in number to the sides or faces of the post, each of said base portions being bent outwardly at right angles to said face, prongs integral with said base portions, and a main supporting-body through which said prongs are extended and beneath which they are bent in a plane parallel to said base portions respectively.

699,716. FLOW. JOHN GARDNER, Dundee, Tex. Filed Nov. 9, 1901. Serial No. 63,399. (No model.)

Claim.—1. A plow, comprising a pair of rearwardly-diverged blades having their forward ends mitered and abutted, and a share secured to the forward ends of the blades and spanning the joint therebetween, whereby the share forms a base connection between the blades, the forward end of the share being formed into a plow-point, and its rear end being projected rearwardly between the blades and bowed upwardly to form a deflector or moldboard.

2. A plow, comprising a pair of rearwardly-diverged blades having their forward ends mitered and abutted, and a share secured to the forward ends of the blades and spanning the joint therebetween, whereby the share forms a connection between the blades, the forward end of the share having its opposite longitudinal edges bowed forwardly to form a point which projects in front of the blades, and the rear end of the share being projected between the blades and twisted upwardly and laterally, one rear corner of the twisted portion being cut away diagonally.

3. A plow, comprising a pair of rearwardly-diverged blades having their forward ends mitered and abutted, a share secured to the forward ends of the blades and spanning the joint therebetween, whereby the share forms a connection between the blades, the forward end of the share being formed into a plow-point, the rear end of the share being extended rearwardly between the blades and bowed or twisted upwardly to form a moldboard, and the intermediate portion of the blade having an opening extending through the joint between the blades for the reception of a fastening for connection with a plow-standard.

4. A plow, comprising a pair of rearwardly-diverged blades having their forward ends mitered and abutted, an attaching-base secured to the under side of the blades and overlapping the joint between the blades, and a share secured to the upper sides of the blades and overlapping the outside of the said joint, the forward end of the share being formed into a plow-point, and the rear portion thereof being extended rearwardly and bowed upwardly to form a moldboard, and a fastening device piercing the share and the attaching-base.

5. A plow, comprising a pair of rearwardly-diverged blades having their forward ends mitered and abutted, an attaching-base secured to the under sides of the blades and overlapping the joint therebetween, a share secured to the upper sides of the blades and overlapping the said joint, the forward end of the share being formed into a plow-point, and the rear portion thereof being extended rearwardly and bowed upwardly to form a moldboard, and a fastening device piercing the share and the attaching-base.

6. A plow, comprising a pair of rearwardly-diverged blades having their forward ends mitered and abutted, an attaching-base having rearwardly-directed members secured to the under sides of the respective blades and provided with a forwardly-directed portion overlapping the under side of the joint between the blades, a share secured to the upper sides of the blades and overlapping the joint therebetween, the forward portion of the share being formed into a plow-point and the rear portion being shaped into a moldboard, and a fastening piercing the share and the rearwardly-directed portion of the attaching-base.

7. A plow, comprising rearwardly-diverged blades, and a base or attaching-frame having substantially parallel members to embrace a standard and located below and projected in rear of the intersected front ends of the blades, and rearwardly-diverged wings projected from the front ends of the members, said wings fitting snugly against the under sides of the blades, and the latter being connected to the wings.

8. In a plow, the combination of rearwardly-diverged blades, a point secured to the intersected ends of the blades, and an attaching base or frame therefor comprising spaced rearwardly-projected members located below the front portions of the blades, and having rearwardly-diverged wings fitting snugly the under sides of the blades, one of the members having a front projection fitting snugly in the angle between the intersected blades, and fastenings connecting the blades to the wings and the point to the front projection of the base or attaching-frame.

9. In a plow, the combination of rearwardly-diverged blades having their front ends mitered and abutted, a share applied to the upper sides of the abutted ends of the blades, the forward end of the share being projected in front of the blades and formed into a point, and the rear portion

of the share being extended rearwardly between the blades and bowed upwardly and laterally to form a deflector or moldboard, one rear corner of the upturned portion being cut away, and a base or attaching-frame, comprising a pair of substantially parallel members located below the forward ends of the blades and having rearwardly-diverged wings projected from the forward ends of the members and fitting snugly the under sides of the respective blades, one of the members having a forward extension fitting the angle between the blades, a fastening piercing the share and the forward projection of the base, and other fastenings connecting the blades to the wings.

699,717. STELLER. San G. STELLER, Chicago, Ill. Filed July 24, 1901. Serial No. 90,000. (No model.)

Claim.—1. A sterilizer comprising a receptacle having double walls including a passage; a boiler completely closed except at its periphery where said boiler communicates with the passage between said walls, and tubes passing through said boiler for the admission of heated gas into said receptacle.

2. In a sterilizer the combination of a receptacle having double walls including a passage, a boiler closed to the atmosphere and communicating with said passage, a set of tubes extending through said boiler for conducting the heating-gas directly through said boiler without deflection into said receptacle and a distributing-plate within said receptacle for spreading said gas after the latter have been introduced within said receptacle.

3. In a sterilizer, the combination of a receptacle consisting of an inner and an outer vessel including a vertically-arranged passage, said passage having openings at the top thereof connecting with the interior of the inner vessel, a boiler beneath said receptacle, the outer wall of said boiler joining the outer wall of said receptacle to thereby prevent the escape of steam directly from said boiler to the atmosphere, said boiler opening into said vertical passage; a set of boiler-tubes extending through said boiler for conducting the heating-gas directly through said boiler into said receptacle, and means for detachably attaching said boiler to said receptacle.

4. In a sterilizer, the combination of a receptacle having double walls including a passage, a boiler beneath said receptacle communicating with said passage, the outer wall of said boiler joining the outer wall of said receptacle to thereby prevent the escape of steam from said boiler directly to the atmosphere, a set of tubes extending vertically through said boiler for conducting the heating-gas through the boiler into the lower extremity of the sterilizing-receptacle, a removable distributing-plate above said tubes, and a diaphragm above said plate having an aperture therein for permitting the upward progress of the heating-gas.

5. In a sterilizer, a receptacle having double walls including a passage between them, in combination with a separate boiler detachably attachable to said receptacle, said boiler being completely closed except at portions communicating with the passage between said walls, and said boiler having a set of vertically-arranged tubes extending therethrough for conducting the heating-gas directly into the said receptacle.

6. In a sterilizer, a pair of hollow cylinders one within another including a passage, said passage being closed at the top and open at the bottom, a boiler, closed except at the bottom of said passage where said boiler communicates with the lower extremity of said passage, apertures in the inner of said cylinders near the top thereof, a cover having a depending flange fitting next to said inner cylinder and apertures in said depending flange, apertures in said inner cylinder and cover, corresponding and communicating when said cover is in one position but being non-communicant when said cover is rotated, said cover thereby constituting a diaphragm for regulating the admission of steam to the heating-chamber.

699,718. ADVERTISING DEVICE. CHARLES F. BARKER, Buffalo, N. Y. Filed Mar. 20, 1901. Serial No. 51,051. (No model.)

Claim.—1. In an advertising device, the combination with the casing having a right-opening therein, of an apron or ribbon movably held in said casing, a rock-shaft, a rock-arm secured to said rock-shaft, a reversible shaft, a ratchet-wheel secured to said reversible shaft, a ratchet-engage-

ment pivotally secured to the rock-arm and adapted for engagement with said ratchet-wheel, means for disengaging the ratchet-engage-ment from the ratchet-wheel as it approaches the end of its operative movement and whereby said segment is caused to remain disengaged until it assumes its normal position, and mechanism intermediate of the movable ribbon and the said reversible shaft, substantially as set forth.

2. In an advertising device, the combination with the casing having a right-opening therein, of a movable apron or ribbon supported in said casing, a rock-shaft, a rock-arm secured to said rock-shaft, a reversible shaft, a ratchet-wheel secured to said reversible shaft, a ratchet-engage-ment pivotally secured to said rock-arm and adapted to engage said ratchet-wheel, a spring-controlled and laterally-projecting pawl secured to said segment, a cam-guide on which said segment rides and which disengages the same from the ratchet-wheel after revolving the latter a predetermined distance, said cam-guide having an upwardly-projecting flange against which the said pawl strikes and whereby it is caused to remain during the operative movement of the segment, said pawl being projected and adapted to ride on said flange during the return movement of the segment, and mechanism intermediate of the reversible shaft and the movable apron, substantially as set forth for the purpose set forth.

3. In an advertising device, the combination with the casing having a right-opening therein, of a movable apron or ribbon adapted to be moved intermittently a predetermined distance, a rock-shaft, a rock-arm secured to said rock-shaft, mechanism intermediate of said rock-arm and the movable apron or ribbon, a cam-guide secured to the casing and having teeth formed thereon and an upwardly-extending flange arranged on one side of said teeth, a dog pivotally secured to said rock-arm which rides over the teeth on the cam-guide during the operative movement of the rock-arm, and a spring-controlled pawl secured to said dog and normally projecting therefrom, said pawl being made to engage and disengage the teeth of the said dog by striking the flange of the cam-guide, and being held in such position until said dog approaches the end of its movement when it is projected and runs on the said flange, on which it rides during the return movement of the dog, thus keeping the latter disengaged from the teeth on said cam-guide during said return movement, substantially as set forth.

4. The combination with the casing having a right-opening therein, of a movable element bearing advertisements located in said casing, a fuel-receptacle, a rock-shaft, a lighting-jet secured to said rock-shaft as to operate the same, a pipe connecting the lighting-jet with the fuel-receptacle, a housing in which the lighting-jet is normally confined, and mechanism intermediate of the rock-shaft and the movable element bearing the advertisement whereby the latter is moved, substantially as set forth.

5. The combination with the casing having a right-opening therein, of a movable apron or ribbon bearing advertisements and adapted to be moved a predetermined distance intermittently, a transparent housing located outside of said casing, a movable lighting-jet normally confined in said housing, mechanism intermediate of said lighting-jet and the movable apron or ribbon whereby the latter is opened by the movement of said lighting-jet, and means whereby said lighting-jet is prevented from returning to its normal position until the said apron or ribbon has reached the end of its predetermined movement, substantially as set forth.

699,719. CONSTRUCTION OF WRESCHE. FRANKLIN STARR, Worcester, Mass., assignor to Loring Case & Company, Incorporated, Worcester, Mass., a Corporation of Massachusetts. Filed Feb. 2, 1903. Serial No. 22,523. (No model.)

Claim.—1. In a wrench, a wrench-handle collar provided with a

curved-bearing cap having an integral inwardly-overhanging lip, a jaw-adjusting screw having a flanged journal laterally interlocking beneath said lip, a counterbalancing key-piece engaging the journal opposite said lip, and means securing said key-piece in position, for the purpose set forth.

2. In a wrench, the handle-collar having an undercut screw-bearing seat with an open undercut cavity extending to the bar-space or collar-opening, into which the flanged screw-journal is interlocked by insertion at the collar-opening and transverse passage to its seat; and an interlocking follower or key-piece fitting said cavity and confining the screw-journal in its bearing, substantially as set forth.

3. The combination, of a wrench-handle frame provided in its collar end with an undercut cavity extending to the screw-axis, and having an inwardly-overhanging lip and round end seat for receiving the journal; the jaw-adjusting screw having a T-shaped journal, and the interlocking key-piece block provided with side lips adapted for engaging beneath said overhanging lip on the handle-frame, and a transversely-secured end with a lip counterbalancing the screw-journal, and a rear end matching the face of the wrench-bar neck.

4. In a screw-wrench comprising a wrench-bar having a straight body, a fixed jaw and a handle-supporting shank with front and rear collar-positioning shoulders, and a movable jaw slidable on said bar; the jaw-adjusting screw having a ratchet and a grooved and flanged stop-journal, a handle-frame fitting upon said bar-shank against said shoulders, and having an inwardly-tipped bearing-seat for said screw-journal with an open channel having undercut sides extending thereto from the collar-openings and a key-piece, or pieces, fitting in said channel with the end thereof confined beneath the collar-positioning shoulder and against the neck of the bar-shank.

699,720. ROTARY ENGINE. STEPHEN SMITH, Glasgow, Scotland. Filed Aug. 2, 1900. Serial No. 24,700. (No model.)

Claim.—1. In a rotary engine, a cylinder, a cam-plate, in combination with a sliding element provided with a circular casing, a segmental packing-piece adapted to rest in the casing and make sliding contact with the periphery of the cam-plate, and an anti-friction roller or rollers within the segmental packing-piece adapted to roll on the periphery of the said cam-plate, substantially as described.

2. In a rotary engine, a cylinder and a movable element in combination with a cam-plate having a diagonal groove containing the peripheral packing consisting of a metallic packing-piece having horns with inclined surfaces, a layer of soft threads packing filling up the space in

the groove below the metallic plate, a metallic supporting-strip below the flange packing and springs arranged at the bottom of the groove to compress the flange packing and press the whole packing outward substantially as described.

3. In a rotary engine a cylinder, a cam-piston, and a movable abutment in combination with a lubricating pumping device operated by the reciprocation of the movable abutment to pump lubricant to the rubbing-surfaces of the abutment and to the interior of the engine, substantially as described.

699,791. BUTTER-SHRETTING MACHINE. FRANKLIN E. SHAWLEY, Waterbury, Conn., assignor to Swift Manufacturing Company, Waterbury, Conn., a Corporation of Connecticut. Filed Dec. 20, 1900. Serial No. 41,061. (No model.)

Claim.—1. In a butter-shrepping machine, having an overhanging arm, a task-containing turret, a reservoir discharging therefrom, a reciprocating plunger, the combined task-receiver and carrier comprising a rod 16 supported in a bearing in the overhanging arm independently of the plunger, a packed arm 17 rigid on said rod adapted to slide with the reservoir to receive a task therefrom and present it beneath the plunger, a spring 21 normally elevating said rod and arm, a crank-arm 20 fixed to turn said rod and permitting longitudinal movement of the rod through it, means to rock said crank-arm, and means to depress said plunger and thereby cause the said plunger to carry the said receiver and carrier with it in its descent away from the reservoir and into proximity to the object to which the task is to be applied, substantially as described.

2. In a butter-shrepping machine of the class described, having an overhanging arm and a reciprocating plunger therein, the combined task-receiver and carrier comprising a rod 16 having a bearing in the overhanging arm independently of the plunger, and capable of longitudinal and rotary movement in said bearing, a packed arm 17 rigid on said rod and a spring 21 normally holding the packed arm in operative alignment with the plunger and beneath it, combined with a crank-arm 20 hinged to the rod and adapted to turn it and also permitting free longitudinal movement of the rod through it, and means to vibrate said crank-arm, substantially as described.

3. In a butter-shrepping machine of the class described, having an overhanging arm and a reciprocating plunger therein, the combined task-receiver and carrier comprising a rod 16 having a bearing in the overhanging arm independently of the plunger, and capable of longitudinal and rotary movement in said bearing, a packed arm 17 rigid on said rod and a spring 21 normally holding the packed arm in operative alignment with the plunger and beneath it, combined with a crank-arm 20 hinged to the rod and adapted to turn it and also permitting free longitudinal movement of the rod through it, a link 24, a crank-arm 24, a cam-disk and connection between said disk and crank-arm, substantially as described.

699,792. HOIST-ING SUPPORT. WILLIAM E. STANLEY, Chicago, Ill., Filed Aug. 26, 1901. Serial No. 73,264. (No model.)

Claim.—1. The combination with a vehicle-top, and a prop-bolt, of a spring-bar pivotally attached at its front end and having its rear extremity bearing against the rear bow, said spring-bar being arranged to engage the prop-bolt when the top is lowered and being provided with an approximately S-shaped portion, the front portion of the spring-bar which rests upon the prop-bolt being located at the top of the S-shaped portion, and the rear portion of the spring-bar being located at the bottom of the said S-shaped portion and the latter being located in rear of the prop-bolt and adapted to be disengaged in unlatching the vehicle-top, whereby its resiliency is increased and the movement of the rear end of the spring reduced to a minimum, substantially as described.

2. The combination with a vehicle-top, and a prop-bolt, of a spring-bar pivotally attached at its front end and having its rear extremity bearing against the rear bow, said spring-bar being arranged to engage the prop-bolt when the top is lowered and being provided with an approximately S-shaped head located in rear of the prop-bolt, the front portion of the spring-bar, which rests upon the prop-bolt, being located at the top of the S-shaped head and the rear portion of the spring-bar being located at the bottom of the said head, whereby the latter is disengaged in unlatching the vehicle-top and its resiliency increased, an anti-friction-roller mounted on the rear end of the spring-bar, and a loop extending around the front of the rear bow and holding the anti-friction-roller against the same, substantially as described.

699,793. CORE-DRIVER FOR ROUND-LAP RAILS. HENRY SWANSON, Chicago, Ill., assignor to the American Cotton Company, New York, N. Y., a Corporation of New Jersey. Filed Mar. 14, 1901. Serial No. 51,288. (No model.)

Claim.—1. In a core-driver for round-lap rails, the combination with a stationary guide for receiving a drift-pin and beneath which the rail is placed, of a weighted driver arranged to fall upon the drift-pin, means for elevating the weighted driver, and means for releasing the weighted driver from an elevated position, substantially as set forth.

2. In a core-driver for round-lap rails, the combination with a stationary guide for receiving a drift-pin and beneath which the rail is placed, of a weighted driver arranged to fall upon the drift-pin, means for elevating

ing the weighted driver, means for releasing the weighted driver from an elevated position, and elastic buffer carried by said guide for receiving the impact of the weighted driver after it has engaged the drift-pin, substantially as set forth.

3. In a core-driver for round-lap rails, the combination with a stationary guide for receiving a drift-pin and beneath which the rail is placed, of a weighted driver arranged to fall upon the drift-pin, means for elevating the weighted driver, means for releasing the weighted driver from an elevated position, and a receptacle for receiving the core after the latter has been driven from the hole, substantially as set forth.

4. In a core-driver for round-lap rails, the combination of a vertical frame, a stationary cross-brace beneath which the hole is placed and having an opening therein for the reception of a drift-pin, vertical guides extending upwardly from said cross-brace, a weight vertically movable on said guides, and means for operating said weight, substantially as set forth.

5. In a core-driver for round-lap rails, the combination of a vertical frame, a stationary cross-brace beneath which the hole is placed and having an opening therein for the reception of a drift-pin, vertical guides extending upwardly from said cross-brace, a weight vertically movable on said guides, means for operating said weight, and buffer-springs surrounding said guides and carried by the cross-brace for receiving the impact of the weight after it has engaged the drift-pin, substantially as set forth.

699,794. EXTENSION-SLIDE FOR TABLE. DR. WILLIAM TRENKLE, Belleville, Canada. Filed Apr. 20, 1901. Serial No. 50,720. (No model.)

Claim.—1. In an extension-slide comprising two members, the combination with a first member provided, for its whole length, with a compound groove, clear of obstruction, continuous therein, the same being provided with two outwardly-flared grooves, a side groove on each side of said compound groove and parallel therewith, formed in said first member for its whole length, the said side grooves designed to receive blocks which operate therein, and a second member provided, for its whole length, with a continuous central channel parallel with its side, a channel-piece rigidly secured in said channel and provided with outwardly-flared flanges, the same having movement in the outwardly-flared grooves of said compound groove, and a side groove on each side of said channel-piece and parallel with the same, formed in said second member for its whole length, the said side grooves of said second member designed to receive blocks which operate therein, of a pair of blocks rigidly secured in one end of each of the side grooves of said first member, and another pair of blocks rigidly secured in one end of each of the side grooves of said second member, the blocks in the side grooves of said first member operating in the side grooves of said second member, and the blocks of said second member operating in their respective grooves in order to prevent the said members from sagging and binding, the said blocks further abutting, as described in order to prevent the said members from being pulled apart longitudinally.

2. In an extension-slide comprising a series of members, the combination with one end member provided, for its whole length, with a compound groove, clear of obstruction, continuous therein, the same being provided with two outwardly-flared grooves, a side groove on each side of said compound groove, formed in said one end member, for its whole length and parallel with said compound groove, the said side grooves designed to receive blocks which operate therein, the central member, the same being provided, for its whole length, with a continuous central channel parallel with its side, a channel-piece rigidly secured in said channel and provided with outwardly-flared flanges, the same having movement in the outwardly-flared grooves of the compound groove of said one end member, a side groove, on each side of said channel-piece, formed in said central member, for its whole length and parallel with said compound groove, the said side grooves designed to receive blocks which operate therein, the said side grooves of said central member being further provided, on their opposite side and for their whole length, with compound grooves clear of obstruction, continuous therein, the same being provided with two outwardly-flared grooves, a side

groove on each side of said compound groove in said central member, and parallel therewith, the said side grooves designed to receive blocks which operate therein, and another end member provided for its whole length with a continuous central channel parallel with its side, a channel-piece rigidly secured in said central channel of said other end member and provided with outwardly-flared flanges, the same having movement in the outwardly-flared grooves of one of said side grooves of said one end member, a side groove on each side of said channel-piece, formed in said other end member for its whole length and parallel with said outwardly-flared groove of said central member, the said side grooves designed to receive blocks which operate therein, of a first pair of blocks rigidly secured in one end of each of the side grooves of said one end member, a second pair of blocks rigidly secured in one end of each of the side grooves formed on each side of the channel-piece of said central member, the second pair of blocks operating in the side grooves in which the first pair of blocks are secured, the first pair of blocks operating in the side grooves in which the second pair of blocks are secured, a third pair of blocks rigidly secured in one end of each of the side grooves formed in said central member on each side of the compound groove formed therein, and a fourth pair of blocks rigidly secured in one end of each of the side grooves of said other end member, the third pair of blocks operating in the side grooves in which the first pair of blocks are secured, and the fourth pair of blocks operating in the side grooves in which the third pair of blocks are secured, the said pairs of blocks operating in their respective grooves in order to prevent the said members from sagging and binding, the said blocks further abutting, as described, in order to prevent the said members from being pulled apart longitudinally.

699,795. GAS-DISTRIBUTING SYSTEM. MAX TRENN and ALBERT LUTHELMAN, St. Paul, Minn.; and Leopoldo assignor to said Trenn. Filed Jan. 12, 1901. Serial No. 48,690. (No model.)

Claim.—1. The herein-described system comprising a source of compressed acetylene gas, in combination with a service pipe or main, a distributing-valve, and said pipe or main containing a fusible pipe-section, as and for the purpose specified.

2. The herein-described system comprising a source of compressed acetylene gas, in combination with a service pipe or main, a distributing-valve, and a fusible pipe whereby said main and valve are connected, substantially as described.

3. The herein-described system comprising a source of compressed acetylene gas, in combination with a service pipe or main, a fusible pipe-section interposed between said source and said main, and a safety gas-distributing pipe provided at a remote point on said main, substantially as described.

4. The herein-described system comprising a source of compressed acetylene gas, in combination with a service pipe or main, a service-tank, a regulating-valve provided in connection therewith, and a fusible section interposed in said main in proximity to said service-tank, substantially as described.

5. The herein-described system comprising a source of compressed acetylene gas, in combination with a storage-tank, a service pipe or main leading therefrom, a distributing-valve, and a fusible pipe-section interposed between said main and said valve, substantially as described.

6. The herein-described system comprising a source of compressed acetylene gas, in combination with a storage-tank, a service pipe or main leading therefrom, a distributing-valve, a fusible pipe-section interposed between said main and said valve, a service-tank supplied with gas from said distributing-valve, a regulating-valve, and a fusible pipe interposed

between said service-tank and said regulating-valve, substantially as described.

7. The herein-described system comprising a source of compressed acetylene gas, in combination with a storage-tank 56 insulated against heat and provided with a fusible valve, a service-pipe leading from said tank to a point of gas distribution and containing a fusible section at each point, as and for the purpose specified.

8. The herein-described system comprising a source of compressed acetylene gas, in combination with a storage-tank, a fusible pipe connection between said source and said tank, a service pipe or main leading from said tank, a distributing-valve remotely situated, and a fusible pipe-section whereby said main and valve are connected, substantially as described.

699,726. CONDENSER FOR STEAM MOTOR-CARRIAGES.
FRANKLIN W. TOWN, Cambridge, Mass. Filed Mar. 24, 1908. Serial No. 10,600. (No model.)

Claim.—1. A condenser for steam motor-carriages consisting of several upright banks of pipes arranged in parallelism at the front end of the carriage-body, the pipes of each bank being disposed in different planes, supports therefor attached to said carriage-body, a pipe leading therefrom from the exhaust-pipe of the engine and a pipe leading therefrom, substantially as described.

2. A condenser for steam motor-carriages consisting of one or more banks of pipes arranged in vertical position at the front end of the carriage-body, channels, supports therefor attached to said carriage-body having means for connecting the bank or banks of pipes thereto, a pipe leading to said condensing-pipes from exhaust-pipe of the engine and a pipe leading therefrom, substantially as described.

3. A condenser for steam motor-carriages consisting of several upright banks of pipes arranged in parallelism at the front end of the carriage-body, the pipes of each bank being disposed in different planes, channels and supports attached to said carriage-body having means for connecting the banks of pipes thereto and also for connecting the several supports together, a pipe leading to said condensing-pipes and a pipe leading therefrom, substantially as described.

4. A condenser for steam motor-carriages consisting of one or more banks of pipes arranged in a vertical position at the front end of the carriage-body, and supports therefor attached to said carriage-body, a pipe leading to said condensing-pipes and a pipe leading therefrom, and an obliquely-disposed plate attached to the upper end of said condensing-pipes, substantially as described.

5. A condenser for steam motor-carriages consisting of one or more banks of pipes arranged in a vertical position at the front end of the carriage-body, supports therefor attached to said carriage-body, a pipe leading therefrom from the exhaust-pipe of the engine and a pipe leading therefrom, and a shield disposed back of said condensing-pipes, substantially as described.

6. A condenser for steam motor-carriages consisting of one or more banks of pipes arranged in a vertical position at the front end of the carriage-body, supports therefor attached to said carriage-body, a pipe leading therefrom from the exhaust-pipe of the engine and a pipe leading therefrom, and a shield disposed back of said condensing-pipes having an opening at or near the bottom and a removable cover therefor, substantially as described.

699,727. HINGE. JAMES H. UPTON, Atlantic, and WILLIAM S. GRAY, Danvers, Mass. Filed May 28, 1901. Serial No. 61,204. (No model.)

Claim.—1. The door-hinge having two bats adapted to be secured to the door-jamb, each bat having two bearings for a pin and relatively long openings between, plates mounted in each bearing, the hinge members secured to the door mounted and vertically adjustable on each plate, and means for each vertical adjustment, substantially as described.

2. The door-hinge herein described, the same comprising hinge mem-

bers secured to the door, suitable bats, plates carried by the bats, having threaded sections, nuts carried upon said threaded sections, those of the upper plate offering adjustable bearing, and that of the lower plate adjustable support to the corresponding hinge members fastened to the door substantially as described.

3. A door-hinge consisting of bats adapted to be secured to the door-jamb, plates mounted in the bats having threaded sections and nuts thereon, members of the hinge secured to the door, one of which members has a bar or arm mounted upon the plate and resting upon the nut, and the other a bar or arm mounted upon the plate to rest upon the nut carried thereby substantially as described.

4. A door-hinge having bats adapted to be secured to the door-jamb, plates mounted therein, hinge members secured to the door pivotally supported by said plates, an arm also pivotally mounted, and resting upon or against a bat secured to the door-jamb, with regard to which arm the door is adjustable, and means for effecting the adjustment substantially as described.

5. A door-hinge comprising in its construction hinge members secured to the door, one of which has an arm attached thereto and extending therefrom to rest upon a bat, means for holding each arm to the bat, bats and plates arranged as to provide suitable rest and mounting for the door members of the hinge and arm thereon, and means for adjusting the door with respect to the said arm, resting upon the bat thereon substantially as described.

6. A door-hinge comprising in its construction hinge members secured to the door, one of which has an arm attached thereto and extending therefrom to rest upon a bat, the door being adjustable with respect to such arm, means for effecting such adjustment, bats with pin-bearings having relatively wide openings between, plates centrally mounted therein offering pivotal support to the door members of the hinge as also to the arm mounted on the bat and nut mounted on the plates, as and for the purpose described.

7. In a hinge for doors and similar uses, hinge members fastened to the door extending across the same, separated from each other, and each of which has a true reinforcement-bar with a stay or bump rod connecting the two members substantially as described.

8. A door or other hinge having two reinforced members, the reinforcement of one of which extends near the inner upper corner of the door and the reinforcement of the other of which extends near the lower outer corner of the door, and a brace or tie rod extending diagonally across the door, connecting said reinforcements near said corners substantially as described.

9. A door or other hinge having two reinforced members, the reinforcement of one of which extends near the inner upper corner of the door and the reinforcement of the other of which extends near the lower outer corner of the door, and a brace or tie rod extending diagonally across the door, connecting said reinforcements near said corners, and means for shortening or lengthening said brace or tie rod substantially as described.

10. A hinge having a member provided with two swinging plate-bearings and a nut, a member provided with a swinging bearing and a nut,

means for clamping or drawing together the members diagonally the door, the hinge bats and plates carried by the bats, the plates and bats being combined to provide a vertical adjustment of the hinge members and nuts with respect to the bats substantially as described.

11. The combination in a hinge of two bats, one of which has a nut for the arm of a hinge member, a plate mounted centrally therein to provide a bearing for the arm of the hinge member above the nut and a bearing below it, the other of said bats having a stationary plate and a movable nut mounted upon said plate, hinge members constructed and shaped as described to engage said plates and nuts as specified, and a clamping device connecting the hinge members with each other as set forth.

12. The combination in a hinge of a yielding arm attached to a hinge member fastened to the door, and extending therefrom to rest securely upon or against a bat secured to the door-frame, with a tie-rod connecting said arm with the door, and means for shortening or lengthening the same as and for the purpose described.

13. The combination in a hinge, of bats adapted to be secured to the door-jamb, plates mounted therein, door members of the hinge pivotally mounted upon said plates, one of which members has a bar or arm attached thereto and extending therefrom to rest upon or against a bat secured to the door-frame, with a brace or tie rod, and means for lengthening or shortening the same connecting said arm with the door, so that the said door may be vertically or laterally adjusted substantially as described.

14. The combination in a door-hinge of bats adapted to be secured to the door-frame, plates mounted therein, hinge members secured to the door pivotally mounted upon said plates, an arm also pivotally mounted, and resting upon or against a bat secured to the door-frame, with regard to which arm the door is adjustable, with means for effecting the adjustment consisting of a tie-rod connecting said arm with the door, and means for lengthening or shortening the same, as and for the purpose described.

15. A door or other hinge having two members fastened to the door, a supplementary arm integrally attached to and suspended from one, extending up to near the inner upper corner of the door, then down to proper angle to rest upon its bat, the other member with reinforcing-arm extending down to near the bottom or outer corner of the door, a brace or tie rod extending diagonally across the door connecting said supplementary arm with the other hinge member secured to the door, means for shortening or lengthening said brace or tie rod, bats, plates whereby the door members of the hinge are pivotally connected to said bats and means for adjusting the hinge members secured to the door as aforesaid with respect to the arms aforesaid so that a vertical or lateral movement may be obtained as described.

16. A door-hinge comprising in its construction hinge members secured to the door, a supplementary arm attached to and extending from one hinge member fastened to the door to rest securely upon or against a bat secured to the door-frame, with respect to which arm the door is adjustable, means for effecting such adjustment consisting of a tie-rod extending diagonally across the door and connecting said supplementary arm with the other hinge member secured to the door, means for shortening or lengthening said tie-rod, bats with plate-bearings having relatively long openings between, plates mounted thereon, whereby the door members of the hinge are pivotally connected to said bats, and nuts mounted upon said plates offering adjustable bearing and support to the hinge members secured to the door as and for the purpose set forth.

699,728. LINOTYPE-CLIP HOLDER. GEORGE E. WALLER, Chicago, Ill. Filed Nov. 22, 1901. Serial No. 94,267. (No model.)

Claim.—1. As an improved article of manufacture, a Linotype-clip holder comprising a pressure member to engage a clip, a pair of spaced resilient jaws, and a single clamping-loop extending outwardly from and common to both of the said jaws, a space being formed between the clamping-loop and the jaws to adapt the latter to be frictionally and slidably as well as freely removable in relation to the side portion of a galley.

2. As an improved article of manufacture, a Linotype-clip holder comprising a pressure-frame having a pair of spaced jaws at one end, and a clamping-loop extending with the said jaws and spaced outwardly from the latter, the jaws and clamping-loop being adapted to removably and

adjustably engage the side of a galley and the jaws to contact with the latter at separated points on the same surface.

3. As an improved article of manufacture, a Linotype-clip holder comprising a pressure-frame to bear against a clip, and a pair of spaced jaws and a clamping-loop, and said jaws being adapted to frictionally and slidably engage the inner and outer faces of one side of a galley.

4. As an improved article of manufacture, a Linotype-clip holder comprising a pressure-frame to bear against a clip, and a pair of spaced jaws and a clamping-loop, said jaws being adapted to bear against the inner and outer faces of one side of a galley, one of the jaws being adapted to provide biting edges.

699,729. SYSTEM OF SUBMARINE CONSTRUCTION. BENJAMIN H. WHEELER, New York, N. Y. Filed Jan. 4, 1908. Renewed Oct. 7, 1901. Serial No. 77,880. (No model.)

Claim.—1. A collar-dam, consisting of separate collar-dam sections of rectangular, circular or other shape, said sections being provided with exterior guideways, pins for guiding said sections and holding them in position, and partition-walls guided in said ways for connecting said collar-dam sections, substantially as set forth.

2. A collar-dam, consisting of a number of separate collar-dam sections of rectangular, circular or other shape, braces connecting the walls of said sections, guide-rollers in said braces, pins in said rollers for guiding the sections into position, and partition-walls connecting the opposite ends of said collar-dam sections, substantially as set forth.

3. A collar-dam consisting of a number of independent collar-dam sections of rectangular, circular or other shape, transverse stiffening-braces in said sections, guide-rollers in said braces, pins in said guide-rollers for guiding and retaining the sections in position, partition-walls connecting said collar-dam sections, and a series of vertically-guided mauling rollers or blades arranged on the walls of the collar-dam sections and partition, substantially as set forth.

4. The combination, with a collar-dam composed of a number of separate collar-dam sections of rectangular, circular or other shape, of pins for holding said sections in position, partition-walls connecting said collar-dam sections, mauling rollers or blades for securing the lowermost collar-dam sections and partitions on the ground, and a water-tight curb connecting the collar-dam sections and partition-walls, substantially as set forth.

5. A collar-dam section composed of an open casing of rectangular, circular or other shape provided with transverse braces having interior guide-rollers, substantially as set forth.

6. A collar-dam section composed of an open casing of rectangular, circular or other shape provided with transverse braces having interior guide-rollers and exterior guideways near the corners, substantially as set forth.

7. A collar-dam section composed of an open casing of rectangular, circular or other shape, provided with transverse braces having interior guide-rollers, exterior guideways near the corners, and exterior projecting brackets on the walls, substantially as set forth.

8. The combination, with a collar-dam, consisting of a number of collar-dam sections secured by pins, of partition-walls between said sections, said sections and partition-walls being provided with projecting brackets, and a transverse water-tight curb connecting said collar-dam sections and partition-walls and composed of curved supporting-ribs resting on said brackets, wire-netting placed on said ribs, and a layer of waterproof material placed over said netting, substantially as set forth.

9. In a system of submarine construction, a temporary arch, extending upon the collar-dam and composed of arched supporting-ribs, wire-netting placed on said ribs and a layer of waterproof material placed over said netting, substantially as set forth.

10. In a system of submarine construction, a temporary arch spanning the collar-dam and composed of arched supporting-ribs, wire-netting placed on said ribs, a layer of this sheet-lead placed over said wire-netting and a layer of waterproof material placed in the layer of sheet-lead, substantially as set forth.

11. In a system of submarine construction, a temporary guard-cover, consisting of wire-netting, sheets of lead spread over said netting, and a layer of waterproof material placed over said sheets of lead, substantially as set forth.

699,780. SYRUP-COOLER. JAMES WHERRY, Rochester, N. Y.
Filed Feb. 26, 1906. Serial No. 706,815. (No model.)

Claim.—1. In a syrup-cooler, a tank, suitable cooling device in said tank; a swinging valve for closing the outlet from the bottom of said tank and a screw-threaded rod for operating said valve passing through a pivot not attached to said tank.

2. In a syrup-cooler, the combination of a tank, suitable cooling device in said tank, a swinging valve for closing an opening at the bottom of said tank, screw-operated means for closing said valve and an independent cam device for forcing said valve upon its seat.

3. In a syrup-cooler, the combination of a tank, suitable cooling device in said tank, a swinging valve adapted to close and open at the bottom of said tank, a socket of pivoted to said valve, a rod resting in said socket and having a screw-threaded portion, a bearing for said screw-threaded portion attached to said tank, means permitting the revolution of the rod in said socket and a slight longitudinal movement of said rod with minimum in the socket, and an independent locking device for locking said valve upon its seat.

699,781. FOLDING UMBRELLA. WILLIAM G. WHERRY, Genl. Pkns. N. Y. Filed Sept. 12, 1906. Serial No. 720,561. (No model.)

Claim.—1. The combination with a tubular portion having a perforation therein and a slot, of a spring-plate comprising a base, a leg adjacent one end of the base and engaged with the perforation of the tubular portion, a spring-plate forming a continuation of the opposite end of the base and lying out of contact with the tubular portion at its rear end, a head upon the forward extremity of the spring-plate and lying in the slot of the tubular portion and adapted for reciprocation therein, and a spring-finger extending from the spring-plate and disposed in the same direction therewith and divergingly therefrom, the extremity of the spring-finger lying against the tubular portion at the opposite side from the perforation to hold the leg in the perforation and to reinforce the spring action of the stem.

2. In an umbrella-rod, the combination with a tubular section, of a rod therein and having a longitudinal line to one end, a perforation in the base of the slot, a latch-tongue disposed in the slot and having a leg at one edge engaging the perforation, the opposite edge of the latch-tongue lying against the inner face of the tubular portion to hold the leg in engagement, a perforation through the tubular portion and the rod, a recess in the spring-tongue aligning with the perforation, and a rivet passed through said perforation and recess to hold the parts in position.

3. In a folding umbrella, the combination with ribs-sections and a spreader, of interlocking and pivotally-connected lock elements carried by the ribs-sections, connections between one of said elements and a spreader for holding the elements in mutual engagement, a recess in one of the elements, and a spring-finger carried by the other element and adapted for engagement with the recess to hold the elements in their locking position, said spring being also adapted to move the elements upon their pivotal connection when they are unlocked.

4. In a folding umbrella, the combination with ribs-sections and a spreader, of a lock element carried by each section and having pivotal engagement with each other, said elements being movable longitudinally with respect to each other to lock and unlock them, connections between the spreader and one of said elements for moving it longitudinally with respect to the other element and a spring carried by one element and adapted for engagement with the other element to move the elements upon their pivotal connection when they are unlocked.

5. The combination with a ribs-section having a grooved lock element fixed therein, of a second ribs-section, having a lock element fixed therein, said second lock element lying in the groove of the first element and having a longitudinal slot, a pivot-pin passed through the walls of said groove and through the slot and adapted to play in the latter to permit mutual longitudinal movement of the elements, a pin carried by the first element, a hook adapted for engagement and disengagement with respect to the pin, connections between a spreader and one of said lock elements to move the latter with respect to the second element to engage and disengage the hook with the pin and a spring-finger carried by one of the elements and adapted for engagement with the other element when the hook is engaged with the pin, said finger being adapted to move the elements on their pivot when the hook is disengaged from the pin.

6. The combination with a ribs-section having a locking element provided with a longitudinal groove, of a second ribs-section having a locking element seated in said groove and having pivotal and longitudinal connection with the first-mentioned element, a pin carried by the first element, a hook carried by the second element and adapted for engagement with the pin to hold the ribs-sections together, a spreader pivotally connected with the first element and adapted to move it longitudinally of the second element to engage and disengage the hook with the pin and a spring-finger carried by one of the elements and adapted for engagement with the other element when the hook is engaged with the pin, said finger being adapted to move the elements on their pivot when the hook is disengaged from the pin.

7. The combination with a ribs-section having a locking element fixed therein and comprising a hook and a spring-tongue, of a second ribs-section having a locking element pivoted to the first-mentioned element, the second element having a recess to receive the spring-tongue and having a pin adapted to engage the hook subsequent to the engagement of the spring-tongue with the recess, and a spreader connected with the second element and adapted to move the pin into and out of engagement with the hook.

8. In a folding umbrella, the combination with inner and outer ribs-sections and a spreader, of interlocking and pivotally-connected locking members carried by the ribs-sections, and a fixed pivotal connection between the outer ribs-section and spreader, whereby said spreader serves to hold the locking members in engagement, and means for engaging the ribs-sections apart when the locking members are disengaged.

9. In a folding umbrella, the combination with an inner ribs-section provided with a locking member formed with a longitudinal slot and a locking-hook, of an outer ribs-section having a second locking member provided with a pair of transverse pins designed respectively for engagement with the slot and hook of the other member, a spreader connected to the inner end of the second locking member to urge said members into and out of interlocking engagement, one of said locking members being provided with a recess, and the other of said members being provided with a spring-finger disposed for engagement with the recess to resist relative longitudinal movement of the locking members.

10. In a folding umbrella, the combination with an inner ribs-section, of an outer ribs-section having a loose pivotal connection intermediate of its ends with the outer end of the inner ribs-section, a spreader having pivotal connection with the inner end of the outer ribs-section, means for locking the outer ribs-section and the spreader to the inner ribs-section, and a spring interposed between the two ribs-sections at a point between the two pivotal connections above stated, said spring serving to effect the swinging of the outer ribs-section when said section is unlocked.

699,782. PRESS. JAMES F. WILLIAMS, Boston, Mass., assignor to Ball and Socket Manufacturing Company, Quabbin, Conn., and Boston, Mass., a Corporation of Connecticut. Filed Dec. 2, 1901. Serial No. 54,327. (No model.)

Claim.—1. In a press, the combination of the frame of the press, a plunger carried thereby, a lever pivoted to the frame to engage the plunger, a toggle beneath the lever pivoted to the frame and to the end of the lever, a crank above the lever, and a draft-link connecting the crank with the toggle.

2. In a press, the combination of its frame having a bed and a die or holder carried thereby, a plunger supported by the frame, a plunger-actuating device comprising a lever pivoted to the frame, a toggle connecting the end of the lever with the frame and arranged beneath it, a shaft above the lever and the toggle, a crank upon said shaft, a link connecting said crank with the toggle, a stop for limiting the extent of movement of the toggle, and a plunger and works returning and holding spring.

3. In a press, the combination of the frame, a plunger, means for moving it in one direction comprising a lever, a toggle below the end of the lever connecting its end with the frame, a shaft above the lever, a handle for turning it, a crank upon said shaft, a draft-link connected with the crank and straddling the lever and toggle and connected with the toggle, and a plunger and works returning and holding spring.

699,782.

699,783. HAND-CULTIVATOR. JAMES F. WILLIAMS, Independent. Filed Sept. 12, 1901. Serial No. 75,126. (No model.)

Claim.—1. A hand-cultivator, comprising wheel-supported draft-beam, angle-plates secured rigidly to the draft-beam, plow-beams, equipped with shovels or plows secured at their front ends substantially with the draft-beam, and a link clamped near one end to the plow-beam and near the other to the angle-plate and extending at an angle to both, substantially as described.

2. A hand-cultivator, comprising draft-beam, wheels journaled at one end of said draft-beam, plow-beams equipped with plows and secured at their front ends substantially with said draft-beam, angle-plates secured to the draft-beam, and a link extending at an angle to and connecting the angle-plate with the plow-beam, substantially as described.

3. A hand-cultivator, comprising an axle, a pair of wheels journaled thereon, a pair of plow-beams equipped with shovels or plows, and pivoted at their front ends on said axle at the outer sides of said wheels, a pair of draft-beams connected together and mounted on the axle outward of the plow-beams, a pair of angle-plates, pivoted on the axle and secured in the draft-beam, and links detachably connecting said plow-beams and plow-beams and extending at an angle to both, substantially as described.

4. A hand-cultivator, comprising an axle, plow-beams equipped with shovels or plows, and mounted at their front ends on the axle, and a pair of draft-beams mounted at their front ends on the axle, and connected at their rear ends by a handle, a pair of angle-plates mounted on the axle at the inner sides of the draft-beams and bolted at their opposite ends to said beams, bolts mounted in the ends of the angle-plates projecting away from the draft-beams, and links engaging said bolts at their front ends and detachably connected to the plow-beams at their rear ends, substantially as described.

5. A hand-cultivator, comprising an axle, plow-beams equipped with plows or shovels, and mounted at their front ends on the axle, a pair of draft-beams mounted at their front ends on the axle, and connected at their rear ends by a handle, a pair of angle-plates mounted on the axle at the inner sides of the draft-beams and bolted at their opposite ends to said beams, a U-shaped link having a series of holes in its front ends, and bolted at its rear end to the plow-beams, bolts mounted in the ends of the angle-plates projecting away from the draft-beams, and engaging certain holes of said link, and clamping-arms engaging the ends of said link, substantially as described.

6. A hand-cultivator, comprising a wheel-supported draft-beam, an angle-plate secured rigidly to the draft-beam, a plow-beam equipped with a shovel or plow and secured at its front end coincidentally with the draft-beam, and a link clamped near one end to the plow-beam and near the other to the angle-plate, and extending at an angle to both, substantially as described.

699,784. ELECTRIC GENERATOR. JAMES H. WHERRY, Battle-creek, Mich., assignor to Electric Sparking and Illuminating Company, Limited, Battle-creek, Mich., a Corporation. Filed Apr. 27, 1901. Serial No. 57,726. (No model.)

Claim.—1. In an electrodynamic generator a stationary element, a shaft, an element adapted to be revolved mounted upon said shaft, a shaft turning freely therein, supports for said shaft, centrifugal weights carried by said shaft, and springs for pressing said weights into contact with said shaft.

2. In an electrodynamic generator, a shaft, an armature mounted upon said shaft, a shaft turning freely therein, supports for the shaft, centrifugal weights having surfaces fitting said shaft, springs for pressing said weights into contact with said shaft, and a means for adjusting said weights.

3. In an electrodynamic generator, a shaft, an element adapted to be revolved mounted upon said shaft, a shaft turning freely therein, supports for the shaft, centrifugal weights having surfaces practically fitting said shaft, a flanged collar fixed to the said shaft, two oppositely-disposed elastic supports fixed to the flange of said collar and including said weights, upon one of which said weights are supported, and a means at the top where the two supports cross for varying the tension of the said support.

4. The combination with an electrodynamic generator, of a driving-shaft or rotary part, a clutch carried by the rotary part of said generator, weights for joining the two parts and suitable springs for holding the same normally in contact with the said driving-shaft or rotary part, whereby in the operation of the generator, the weights will release the clutch when a predetermined speed is reached and prevent the more rapid rotation of the revolving part.

5. In a vehicle-lamp the combination of an electrodynamic generator, a shaft, an element thereof mounted upon said shaft and adapted to be revolved, a vertical shaft adapted to turn freely therein, centrifugal weights having surfaces practically fitting said shaft, an elliptical spring to which said weights are attached, a support over said spring and a screw carried by said support, for varying the tension of said spring.

699,785. BUILDING CONSTRUCTION. HARRY A. WISNER, Columbus, Ohio. Filed Dec. 2, 1906. Serial No. 64,322. (No model.)

Claim.—1. In a building construction a building-block of concrete or similar material, said block having formed therein vertical spaced openings and a joint-receiving recess between said openings and each end of said block having formed therein the open half-rooms &c as described, substantially as specified.

2. In a building construction, the combination with two rows of blocks arranged one upon the other, said blocks having formed therein registering openings 2 which extend vertically through the same and hor-

ing joint-receiving recesses formed partly in blocks of the lower row and partly in blocks of the upper row, substantially as specified.

2. In a building construction blocks of concrete or similar material adapted to be supported upon each other, said blocks having registering openings formed therethrough, the blocks of one horizontal row having joint-receiving recesses between their openings and the blocks below said joint-receiving blocks having solid partitions between their openings and beneath said recesses whereby a solid joint-support is provided vertically below said joints, substantially as specified.

699,736. CLOTHES-LINE. ARTHUR A. WOODSTOCK, TRENTON, Victoria, Australia. Filed Aug. 17, 1901. Serial No. 73,414. (No model.)

Claim.—The herein-described improved clothes-line consisting of the combination of the single wire doubled on itself to form two strands A A, metal clasp B adapted to be slid along the line and hold the two strands together, clasp C and C' supporting the line from posts C' and C'', winding-drum as D, furnished with pawl D' and ratchet-wheel D'' all assembled and arranged substantially as described.

699,737. FLY-KIT FOR SCREENS. CHARLES F. WORKER, Ottawa, Iowa. Filed Apr. 24, 1901. Serial No. 67,597. (No model.)

Claim.—1. In a fly-kit for screens, the combination of two bars rigidly connected together and spaced apart, a slit formed between said bars narrowing toward the exterior of the door, and a conical recess in each edge of said slit so shaped that both edges thereof slant toward the exterior opening of the slit.

2. The combination of a screen-frame formed with a head-bar, two bars fixed to said screen-frame and spaced apart, the edges of the bars being beveled to form a slit, the slit and the lower bar overlapping the lower edge of said head-bar and a screen on said frame, the upper edge of said screen being bent within the slit and fixed to the lower bar, the beveled edges of the bars being formed with concave opening to said slit.

699,738. DRAWING INSTRUMENT. MAX C. RAME, New Haven, Conn. Filed Dec. 20, 1901. Serial No. 67,598. (No model.)

Claim.—1. The combination with a flat drawing instrument, adapted to be reversed face for face, of a handle mounted thereon, and movable through the instrument to project above whichever face of the instrument is uppermost.

2. The combination with a flat drawing instrument, adapted to be reversed face for face, of a handle mounted thereon, and movable through the instrument from one face to the other according to the face thereof that is uppermost so that the handle projects above the uppermost face of the instrument, and lies flush with the lower thereof.

3. The combination with a flat drawing instrument, adapted to be reversed face for face, of a sliding handle mounted in the instrument at a right angle to the plane thereof and formed at its ends with steps which limit the movement of the handle in either direction, whereby when the instrument lies on one face the handle will project above its opposite face, and vice versa.

4. The combination with a flat drawing instrument adapted to be reversed face for face, of a hatching handle mounted in the instrument, provided with steps at its ends and sliding to project beyond the opposite faces of the instrument according to which is uppermost.

5. The combination with a flat drawing instrument, of a hatching handle mounted therein, a stop-piece located in the said handle, and a sliding handle mounted in the handle and provided at its ends with steps engaging with the said stop-piece for limiting the movement of the handle in either direction.

699,739. COMBINED PHOTOGRAPHING AND VIGNETTING FRAME. WILLIAM ARTHUR and WILLIAM R. O. CHAMBER, Southampton, England. Filed July 15, 1901. Serial No. 68,485. (No model.)

Claim.—The improved vignetting attachment for photographic-printing frame comprising a frame a fitted with legs b formed with slots c, thumb-screws c engaging with said slots for fixing the frame a to the printing-frame, and the light-diffuser A held in position by clips d, in combination with the printing-frame b provided with strips f and plates g formed with arrow-heads, the back h, stop n, marks a, and pivoted plate p, substantially as described.

699,740. ROTARY ENGINE. JOHN R. ANDERSON, Lima, Pa. Filed Nov. 14, 1900. Serial No. 34,000. (No model.)

Claim.—1. In a reciprocating rotary engine, a circular casing for the cylindrical cylinders having a groove communicating with the outer ends of the cylinders, a pipe running from the space between pistons to the groove and a three-way valve at the intersection of the pipe with the groove, substantially as described.

2. In a rotary engine, the combination of a stationary crank-shaft, a pair of pistons connected together by means of a cross-head that connects slidably with the crank of the crank-shaft, a pair of quarter-balls embracing the crank, a pair of slide-bars containing the quarter-balls

and fitting in the slot of the cross-head, pyramidal wedges between the quarter-balls and the slide-bars and curves in the small ends of the wedges, substantially as and for the purpose described.

699,741. HYDRAULIC. LOUIS A. RAMM and LOUIS J. RAMM, Louisville, Ky. Filed Jan. 14, 1902. Serial No. 83,484. (No model.)

Claim.—In a syphon, the combination of lenses, studs having threaded longitudinal sockets and intersecting transverse openings, guards, each having a cheek and projecting wings, a spring having an upwardly-bowed center and rearwardly-extending ends formed with horizontal coils and entering said transverse openings, and curves passing through the cheeks of the guards and entering the threaded sockets of the studs to secure the guards thereto, and impinging against the ends of the springs to hold the same seated in said openings, substantially as set forth.

699,742. ADDRESSING-MACHINE. FRANK D. BRIDGES, Invented. N. Y. Filed Feb. 15, 1902. Serial No. 83,485. (No model.)

Claim.—1. The combination with printing mechanism and a card-magazine, of rotary card-feed mechanism, continuously acting and independent of the printing mechanism, said feed mechanism being operatively arranged between the magazine and printing mechanism, as specified.

2. The combination with printing mechanism and a card-magazine, of rotary card-feed mechanism continuously acting and separated from the printing mechanism, but operatively arranged to feed the cards from the magazine, as specified.

3. The combination with printing mechanism and a card-magazine, of rotary card-feed mechanism continuously acting, said feed mechanism being arranged between the magazine and printing mechanism to cooperate therewith as a separate and independent device.

4. The combination with printing mechanism and a card-magazine, of rotary card-feed mechanism continuously acting, said feed mechanism being arranged between the magazine and printing mechanism to cooperate therewith as a separate and independent device, and a second magazine, comprising card-carrying guides extending from the feed to the printing mechanism.

5. The combination with printing mechanism and a card-magazine, of rotary card-feed mechanism continuously acting, said feed mechanism being arranged between the magazine and printing mechanism to cooperate therewith as a separate and independent device, and a second magazine, comprising card-carrying guides extending from the feed to the printing mechanism, the entrance to the second magazine being constructed to the approximate thickness of the card.

6. The combination with printing mechanism and a card-magazine, of rotary card-feed mechanism continuously acting, said feed mechanism being arranged between the magazine and printing mechanism to cooperate therewith as a separate and independent device, strippers for the cards and a second magazine, comprising card-carrying guides extending from the feed to the printing mechanism.

7. The combination with printing mechanism and a card-magazine, of rotary card-feed mechanism continuously acting, said feed mechanism being arranged between the magazine and printing mechanism to cooperate therewith as a separate and independent device, and comprising a series of projections radially disposed about and carried by a rotatable shaft.

8. In a stencil-printing machine, the combination with card-magazine and stencil-printing mechanism, of a card-feeding device comprising twin disks, toothed to engage the cards and arranged in operative relation to the magazine, one of the magazines extending from the point of feed to the printing mechanism, as specified.

9. In a stencil-printing machine, the combination with card-magazine and stencil-printing mechanism, of a card-feeding device, comprising twin disks, toothed to engage the cards and arranged in operative relation to the magazine, and card-strippers cooperating with the disks, as specified.

10. In a stencil-printing machine, the combination with card-magazine and stencil-printing mechanism, of a card-feeding device, comprising twin disks, toothed to engage the cards and arranged in operative relation to the magazine, one of the magazines extending from the point of feed to the printing mechanism, and card-strippers cooperating with the disks.

11. In a stencil-printing machine, the combination with a vertically-disposed card-receiving box arranged in operative relation to the discharge end thereof, of a movable inclined bottom frictionally contained within the box and an automatic feed for adjusting the bottom according to the number of cards entered, as specified.

12. In a stencil-printing machine, the combination with a vertically-disposed card-receiving box arranged in operative relation to the discharge end thereof, of a movable bottom frictionally contained within the box and an automatic feed for adjusting the bottom according to the number of cards entered, and one or more projections entering the box as card-receivers, as specified.

13. In a stencil-printing machine, the combination with a vertically-disposed card-receiving box arranged in operative relation to the discharge end thereof, of a movable bottom frictionally contained within the box, a series of springs secured to the movable bottom and bearing against the inner walls of the box, whereby the bottom is frictionally supported, and an automatic feed device for adjusting the bottom according to the number of cards entered, as specified.

14. In a stencil-printing machine, the combination with a card-receiving box arranged in operative relation to the discharge end thereof, of a movable bottom frictionally contained within the box, a series of springs secured to the movable bottom and bearing against the inner walls of the box, whereby the bottom is frictionally supported, and an automatic feed device for adjusting the bottom comprising a vibrating arm relatively disposed to engage the cards within the box and suitable gearing for transmitting the requisite motion for vibrating said arm, as specified.

15. The combination of a rotary printing mechanism, a rotary stencil-card-feed mechanism separate from the printing mechanism, and straight slotted guides extending from between the two and tangential to all the rotating elements comprised therein.

16. The combination of a continuously-rotating, printing mechanism, a continuously-rotating stencil-card-feed mechanism, and two oppositely-arranged slotted guides between which the card passes from feed mechanism to printing mechanism, whereby said cards are positively held in line at every point of their progress from feed to printing mechanism.

699,743. BRASS-TIP FOR PENCIL. WILLIAM E. BROWELL, Littleton, Mich. Filed Aug. 20, 1901. Serial No. 73,993. (No model.)

Claim.—1. In a pencil-tip, the combination of a sleeve A slotted at one end to fit on the upper end of a pencil, the other end of which is slotted into jaws B which are bent slightly inward, one of said jaws being bent to form a leg B'; said jaws adapted to receive an elongated piece of elastic ename material; an external sleeve C containing a detent U for engaging leg B' embracing the said jaws and contacting with the same sufficiently to crowd them into the yielding ename material, whereby the said external sleeve is adjustable back and forth over the said ename material, for the purpose specified.

2. In a pencil-tip, the combination of a sleeve A slotted at one end to fit on the end of a lead-pencil, the other end of which is slotted into jaws B which are bent slightly inward and adapted to receive an elongated piece of elastic ename material; an external sleeve C embracing the said jaws and contacting with the same sufficiently to crowd them into the yielding ename material whereby said external sleeve is adjustable back and forth over said jaws and over the ename material, for the purpose specified.

2. In a pencil-tip, the combination of a sleeve adapted to fit on the end of a lead-pencil, the upper end of which is divided into jaws which are bent slightly inward and adapted to receive an elongated piece of elastic crumple material of such size as to force the jaws slightly outward; an external sleeve embracing the jaws and extending beyond the same and covering the same into the crumple material to retain it securely and adjustably back and forth over the same, for the purpose specified.

699,744. TROLLEY-WHEEL. GEORGE R. CHAPMAN, GEORGE L. BROWN, and JOHN H. WHEEL, Cleveland, Ohio. Filed July 10, 1901. Serial No. 69,458. (No model.)

Claim.—1. In combination, a trolley-pole and harp, a trolley-wheel supported thereby, and a contact-piece between the harp and the wheel having both lateral and tangential contact-surfaces with the wheel.

2. In combination, a trolley-pole and harp, a trolley-wheel supported in bearings on the harp, an axle for the wheel, a hub or shoulder extending from the side of the wheel, and a contact-piece between the wheel and the harp having two lines of contact, one laterally with the wheel and the other tangentially with the hub or shoulder.

3. In combination, a trolley-pole, a harp at the upper end thereof, a bearing-box on each arm of the harp, a wheel between the bearing-boxes having an axle extending into the bearing-box, and a contact-ring hinged to the inner wall of the bearing-box and adapted to contact with the wheel.

4. In combination, a trolley-pole, a harp at the upper end thereof, a bearing-box on each arm of the harp, a wheel between the bearing-boxes having an axle extending into the bearing-box, and a contact-ring hinged to the inner wall of the bearing-box and adapted to yieldingly contact with the wheel.

5. In combination, a trolley-pole, a harp at the upper end thereof, a bearing-box on each arm of the harp, a wheel between the bearing-boxes having an axle supported in the bearing-box, and a contact-ring hinged to the inner wall of the bearing-box, the hinged connection being such that the ring has longitudinal and radial movement relative to the axle, so that it contacts with the side of the wheel and with the periphery of the axle or hub.

699,745. FLOOR-POLISHING BRUSH. DANIEL I. OGDEN, Watery, N.H. Filed Apr. 20, 1901. Serial No. 69,399. (No model.)

Claim.—1. A belting device for gyratory belting-machines, comprising superposed frame members having bottoms provided with cor-

responding tailings-discharge openings, the bottom of the upper member being formed by a screen, and the contiguous edges of the frames being provided with a notch and projection interlocking connection to prevent edgewise separation of the frames.

2. A belting device for gyratory belting-machines, comprising superposed frames, having bottoms which are provided with corresponding tailings-discharge openings, the bottom of the upper frame member being formed by a screen, the upper edge of the lower frame member being provided with notches, and the bottom edge of the upper member being provided with projections corresponding to and adapted to fit snugly within the notches of the lower frame to prevent edgewise separation of the frame members.

3. As a new article of manufacture a belting element for gyratory belting-machines, comprising a skeleton frame having its upper edge provided with sets of aligned notches, a bottom secured to the lower edge of the frame and having a discharge-opening formed therein at one end thereof, and bottom-supporting cleats secured to the lower edge of the frame across the outer side of the bottom and disposed to correspond with the respective sets of notches in the upper edge of a similarly-constructed adjacent frame.

4. The combination with a belting-device, the cloth of which presents an unobstructed and unbroken plane throughout its entire upper surface, and sleeve-cloth-supporting bars or cleats secured to the under side of the frame and arranged transversely and longitudinally thereof, of a collecting-box having recesses formed in its upper edges, with which recesses the said bars or cleats on the belting-device detachably engage when the device and the box are assembled, thereby to prevent lateral and longitudinal play of the frame when in operation.

5. The combination with a belting-device having sleeve-cloth-supporting bars secured to the under side of the frame, of a collecting-box having its upper edges provided with recesses with which the bars of the belting-device detachably engage when the device and the box are assembled, the connection between the bars and the recesses serving to effect a stable juncture between the two parts, and at the same time to prevent lateral or longitudinal play of the frame when in operation.

6. A belting device for gyratory belting-machines, comprising a plurality of belting members having corresponding tailings-discharge openings, and detachable interlocking means between the frames of consecutive members so as to prevent edgewise play thereof.

7. As a new article of manufacture, a belting element for gyratory belting-machines, comprising a skeleton frame having notches formed in one edge, and projections carried by the opposite edge thereof, and a bottom secured to the lower edge of the frame and having a discharge-opening formed in one end thereof.

699,746. MAIL-BOX. DARWIN R. CHAPMAN, English, Ohio. Filed Mar. 2, 1902. Serial No. 69,451. (No model.)

Claim.—1. In a mail-box of the character described, the combination with a suitable base; of a tilting frame or support, a box carried by the support, a cover for the box, and means for opening and closing the cover upon the tilting of the support, substantially as described.

2. In a mail-box, the combination with a suitable base; of a tilting frame or support, a box carried thereby, a hinged or pivoted cover for the box, and connections between the cover and base for automatically opening or closing said cover upon the forward or backward tilting of the box on said support, substantially as specified.

3. In a mail-box of the character described, the combination of a base-support provided with a rearwardly-extending arm, a tilting frame mounted upon said support, a box carried by the frame, a hinged or pivoted cover for the box, an arm projecting rearwardly therefrom, a link connecting the arms of the support and cover, whereby when the box is moved forwardly or rearwardly on its tilting frame, the cover is automatically opened or closed, substantially as specified.

4. In a mail-box of the character described, the combination of a

base-support, a tilting frame mounted thereon, a box carried by the frame, a hinged or pivoted cover for the box, a link connection between the support and cover for automatically opening and closing the cover upon the forward and backward swinging of the box upon its tilting frame, and a signal adapted when in one position to rest upon the box-cover, and in its other position to be supported by the link, substantially as specified.

699,747. RAILWAY-FRAME LUBRICATOR. FRED M. DE LAFF, Chicago, Ill. Filed Oct. 9, 1901. Serial No. 70,128. (No model.)

Claim.—1. Is a lubricator for railway-cars the combination with an injector-pipe of a steam-pipe, inserted into the head of the boiler and extending downward underneath the cab and to the trunk of the tender, a motion-valve in said pipe, a T connecting said motion-valve with said injector-pipe and valves to operate said lubricator substantially as specified.

2. Is a lubricator for railway-cars a steam-induction pipe connected with the head of boiler of the engine a motion-valve connecting with said induction-pipe, a T connecting said motion-valve with the water-injector pipe on the boiler of the engine and means to operate said device substantially as specified.

699,748. FILE. HENRY F. BULLOCK, Chicago, Ill. Filed Dec. 26, 1901. Serial No. 67,778. (No model.)

Claim.—1. Is a file for the temporary preservation of newspapers and like publications the combination comprising a staff formed of one piece of material, preferably of wood, having a longitudinal channel triangular in form, the interior and exterior angles of said channel being rounded, a handle affixed to one end of said staff, a cap adapted to be attached to and to be removable from the other end of the staff, the said cap having a central aperture in line with the longitudinal center of the staff, and a bar or file adapted to extend longitudinally through the channel in the staff and through the aperture in the cap, the said bar or file having a cut-off end and an eye, the said eye and cut-off being arranged to engage and to hold the cap in a permanent movable position on said bar or file, substantially as described.

2. Is a file of the class described the combination of a staff having a longitudinal channel triangular in form, and having a handle affixed to one end of said staff, with a cap adapted to fit on the other end of said staff, and a bar or file having an offset end and an eye, that part of said bar or file between the offset end and eye being adapted to pass through an aperture in said cap and to form a permanent central bearing on which said cap is free to be revolved, substantially as described.

699,749. LOADING OR UNLOADING APPARATUS. DAVID J. FARMER, Butler, Tenn. Filed Nov. 14, 1901. Serial No. 69,395. (No model.)

Claim.—1. Is a loading and unloading apparatus of the character described, a supporting-frame comprising longitudinal side, cross-bars connecting the side and projected at opposite sides thereof, and pendant finger-boards connected to the opposite ends of the cross-bars, and check-bolting means hinged to the frame.

2. Is a loading and unloading apparatus of the character described, a main supporting-frame comprising opposite longitudinal side, cross-bars connecting the side and projected at opposite sides thereof, finger-boards carried by the opposite ends of the cross-bars, longitudinal brace-bars applied to the upper edges of the finger-boards and the cross-bars, opening-blocks interposed between the side and the adjacent finger-boards, and a plurality of check-bolting means hinged to the respective longitudinal brace-bars.

3. Is a loading and unloading apparatus, the combination with a vehicle, of a check-bolting device hinged thereto, and a substantially U-shaped standard pivoted at opposite ends to the bolting device to engage the ground and support said device in position for engagement with a check, and a flexible brace extending between the bolting device and the swinging standard.

4. Is a loading and unloading apparatus, the combination with a vehicle, of a bolting-frame hinged to the vehicle, check-engaging means carried by the frame, a lever mounted upon the frame to swing the same upwardly upon its hinged connection, and a substantially U-shaped swing-

ing standard having its opposite ends pivoted to opposite sides of the bolting-frame, and provided with a flexible brace extending between the standard and the rear portion of the bolting-frame.

5. Is a loading and unloading apparatus, the combination with a supporting-frame, of a bolting device hinged thereto and capable of swinging in a vertical direction, and an extending lever rigidly carried by the bolting device, the top of the supporting-frame lying in the path of the swing of the lever and forming a stop to limit the movement thereof, whereby said lever forms a prop to support the bolting device in its elevated position.

6. Is a loading and unloading apparatus, a substantially rectangular vertically-swinging bolting-frame, a winding-drum mounted thereon, pairs of guide-rollers mounted upon the outer end of the frame, and a looped check-embolting cable projected in front of the outer end and having its opposite portions working between the members of the respective pairs of guide-rollers, and its opposite ends connected to the winding-drum, whereby the cable and the outer end bar cooperate to embrace a check.

7. Is a loading and unloading apparatus, a vertically-swinging substantially rectangular bolting-frame, having a transversely-disposed winding-drum, a lever projected upwardly from the inner end of the frame, a brace extending between the lever and the outer corner of the frame, a swinging standard normally pendant from the frame, a flexible brace connection between the standard and the rear end of the frame, guides upon the upper side of the outer end of the frame, teeth projected from the under side of said outer end, and a looped check-embolting cable having its opposite portions working through the respective guides and also connected to the drum.

8. Is a loading and unloading apparatus, the combination with a frame comprising opposite longitudinal side, cross-bars connecting the same and projected at opposite sides thereof, finger-boards carried by the opposite ends of the cross-bars, and check-bolting frames hinged to opposite sides of the frame, each bolting-frame having an opening-lever, a winding-drum, guides upon the outer end of the frame, a check-embolting looped cable having its opposite portions working through the respective guides and also connected to the drum, and a supporting-standard and swing from the frame and adapted to engage the ground for the support of the frame.

9. Is a loading and unloading apparatus, the combination of a frame comprising opposite longitudinal side, cross-bars connecting the same and projected at opposite sides thereof, finger-boards carried by the outer ends of the cross-bars, and longitudinal brace-bars applied to the outer end portions of the cross-bars, each brace-bar having pairs of notches formed in the upper outer edge thereof, hinge-connections secured to the brace-bars and adjacent to the notches, substantially rectangular vertically-swinging bolting-frames at opposite sides of the main frame, each bolting-frame comprising opposite longitudinal bars and end cross-bars, the rear cross-

bar being disposed inwardly from the rear ends of the side bars, said rear ends of the side bars working in corresponding notches of the main frame, a hinge-plate pivoting the rear ends of the hoisting-frame and engaging the hinge-sockets, a winding-drum mounted upon the hoisting-frame, guides carried by the outer end of said frame, a shock-absorbing looped cable having its opposite portions working through the respective guides and connected to the drum, a swinging supporting-standard carried by the hoisting-frame, a flexible connection between the standard and the rear end of the frame, and a lever rigidly connected to the hoisting-frame.

10. The combination with vehicle-holsters having standards rising therefrom, of a loading and unloading apparatus having a main supporting-frame comprising opposite longitudinal side members supported upon the holsters and at the inner ends of the standards, cross-bars connecting the side members and projected at opposite sides thereof, flanges carried by the opposite ends of the cross-bars to fit upon the outer sides of the vehicle-wheels, and vertically-swinging shock-holding frames hinged to opposite sides of the main supporting-frame.

11. In a loading and unloading apparatus, the combination with a vehicle, of a hoisting device hinged to the vehicle and adapted to assume a substantially horizontal position for engagement with a shock, means for elevating the hoisting device independently of the movement of the vehicle, and a pendant swinging supporting-standard carried by the hoisting device with its lower end capable of resting upon the ground to support the hoisting device when the latter is swung outwardly into a substantially horizontal position for engagement with a shock.

12. In a loading and unloading apparatus, the combination with a vehicle, of a hoisting device hinged thereto, means for supporting the hoisting device in a substantially horizontal position when swung outwardly from the vehicle into position for engagement with a load, and means for elevating the hoisting device upon its hinged support independently of movement of the vehicle.

13. In a loading and unloading apparatus, the combination with a vehicle, of a hoisting device hinged thereto, means for supporting the hoisting device in a substantially horizontal position when swung outwardly from the vehicle into position for engagement with a load, and means for elevating the hoisting device upon its hinged support independently of movement of the vehicle.

14. In a loading and unloading apparatus, the combination with a vehicle, of a hoisting device hinged to one side and capable of swinging transversely thereof, propping means swung from the hoisting device to support the latter in a substantially horizontal position when swung outwardly from the vehicle for engagement with a load, and an upstanding lever carried by the hoisting device for swinging the same upwardly upon its hinged connection independently of a movement of the vehicle.

15. In a loading and unloading apparatus, the combination with a supporting-frame, of a hoisting device hinged thereto, and a lever rigidly carried by the hoisting device and inclined upwardly and outwardly toward the free end thereof, the top of the supporting-frame lying in the path of the inward swing of the lever, whereby the latter forms a prop to support the hoisting device in an inwardly and upwardly inclined position when elevated.

699,750. WRAPPING-MACHINE. JOHN H. PHILIPS, Pittsburg, Pa. Filed Apr. 20, 1901. Serial No. 55,145. (No model.)

Claim.—1. A wrapping-machine, consisting of a frame having folding mechanism, a wrapper-feeding device, a depending shoe for temporarily holding an article to be wrapped, and means for swinging the shoe from underneath said article preparatory to its being wrapped, as set forth.

2. A wrapping-machine, consisting of a frame and folding apparatus, a wrapper-feeding device, a depending swinging shoe on which an article is fed and temporarily held, arms designed to depress the article and wrapping-paper onto a folding-table, and means actuated by one of said arms, for depositing the article to be wrapped on the wrapping-paper by withdrawing said shoe, as set forth.

3. A wrapping-machine, consisting of a frame and folding mechanism, a wrapper-feeding device, a depending swinging shoe mounted over the wrapping-paper, and designed to temporarily hold the article to be wrapped over the paper, arms for engaging the article, one of said arms adapted to swing said shoe from under the article to be wrapped, and means for depressing the article and paper beneath same onto a folding-table, as set forth.

4. A wrapping-machine consisting of a frame and folding mechanism, an intermittent wrapper-feeding device for advancing the paper to a position on which an article is deposited, means for cutting the wrapping-paper a measured length, a yoke rotated to the frame, a swinging shoe pivoted thereto, and having an angled and adapted to temporarily support the article to be wrapped, the pivoted arms for engaging the article and depressing same with the wrapping-paper onto a wrapping-table, one

of said arms designed to throw the shoe back to free the article as the arms approach each other, as set forth.

5. A wrapping-machine, consisting of a frame and folding mechanism, an intermittent wrapper-feeding mechanism for advancing a piece of paper to a position to receive an article to be wrapped, means for cutting the paper a measured length, a yoke secured to the top of the frame, a swinging shoe having a projection designed to temporarily support the article to be wrapped, a plate pivoted to swing with said shoe, and arms having angled ends which engage and depress the article to be wrapped, one of said arms designed to contact with and swing said plate and the shoe centered thereto backward to free the shoe from the article, as set forth.

6. A wrapping-machine, consisting of a frame and folding mechanism, an intermittent wrapper-feeding mechanism for advancing the paper to a position to receive an article to be wrapped, means for cutting the paper to a measured length, a yoke secured to the frame, a shoe having an angled projection, and pivoted within said yoke, a plate mounted to swing with said shoe, and guided by a pin working in a slot in one of the arms of the yoke, the edge of said plate being inclined, the pivoted arms with plates secured to the ends thereof which are adapted to engage over the article to depress same onto a wrapping-table, one of said arms adapted to contact with said plate and swing same together with said shoe rearward to release the article and deposit same on the wrapping-paper, as set forth.

7. A wrapping-machine, comprising a frame and folding mechanism, an intermittent wrapper-feeding mechanism, for advancing the paper to a position to receive an article to be wrapped, a reciprocating paper supporting and guide plate, means for operating same, a swinging shoe for temporarily supporting the article to be wrapped over the wrapping-paper which has been cut to a measured length, and mechanism for swinging the shoe rearward and for operating said guide-plate, as set forth.

8. A wrapping-machine comprising a frame and folding mechanism, paper-feeding means, a reciprocating plate mounted on the frame of the machine and having two blades K' and K'' spaced apart, a tilting lever engaging said spaced plate, and adapted to reciprocate the same, and means for tilting said lever, as set forth.

9. A wrapping-machine, comprising in combination with the frame, the paper-feeding mechanism, means for cutting the paper, swinging arms which are adapted to automatically grip an article which has been deposited upon the wrapping-paper, means for operating said arms and depress the same with the wrapping-paper, and means for folding the opposite longitudinal edges of the wrapping-paper about an article resting on a folding-table, as said swinging arms are raised to their highest position, as set forth.

10. A wrapping-machine, comprising in combination with the frame of the machine, means for feeding the paper to a position to receive an article to be wrapped, pivoted and vertically-reciprocating arms adapted to grip the article which has been superimposed upon the wrapping-paper and depress the same with the wrapping-paper, means for operating said arms, a wrapping-table, and means for folding one edge of a wrapping-

paper resting on said table on which an article to be wrapped rests, slightly in advance of the opposite flap, said folding being effected in the upward throw of said reciprocating arms.

11. In a wrapping-machine, the combination with the frame, reciprocating pivoted arms, which are adapted to engage and depress an article to be wrapped, which has been superimposed upon the wrapping-paper, means for operating said arms, a stationary wrapping-table, horizontally-movable folding-blades mounted above said table, and levers which are adapted to actuate said blades, one in advance of the other, as said swinging arms are raised to depress a following article to be wrapped, as set forth.

12. A wrapping-machine, comprising in combination with the frame, vertically-movable swinging arms, which are adapted to engage and depress an article to be wrapped, which has been previously superimposed upon a piece of wrapping-paper, means for operating said arms, a driving-shaft and connection between said shaft and the swinging arms for operating the latter, folding-blades adapted to be actuated, one in advance of the other, as said arms are raised to their highest position, as set forth.

13. A wrapping-machine, comprising in combination with the frame, an operating-shaft, a reciprocating cross-head, pivoted and swinging arms carried by said cross-head, connections between said shaft and cross-head for operating the latter, and means for tilting or swinging said arms as the cross-head reciprocates.

14. A machine for wrapping articles, comprising in combination with the frame, a driving-shaft, a cam-wheel mounted thereon, a cross-head and connection between same and said cam-wheel for reciprocating the cross-head, folding-blades, which are driven forward by said cam-wheel as the cross-head rises, pivoted and swinging arms carried by the cross-head, and adapted to be thrown outward as the cross-head is raised, and means for throwing the arms toward each other as they approach their highest position, as set forth.

15. A machine for wrapping articles, comprising in combination with the frame, a driving-shaft, cam-wheel mounted thereon, a reciprocating cross-head, horizontally-disposed folding-blades, which are driven forward by the cam-wheel, as said cross-head rises, pivoted arms mounted on said cross-head, and end-folding blades carried by said arms, as set forth.

16. A machine for wrapping articles, comprising in combination with the frame, a driving-shaft and cam-wheel rotating therewith, a reciprocating cross-head, connections between same and said driving-shaft, the side-folding flaps actuated by said cam-wheel, the pivoted arms carried by the cross-head, and means for operating said arms as the cross-head reciprocates, an edge-folding blade secured to each arm, adapted in turn to fold the opposite edge flaps of the wrapper, as said arms descend, as set forth.

17. A machine for wrapping articles, comprising in combination with the frame the driving-shaft, the cam-wheel rotating therewith, cross-head and connections between same and said cam-wheel, the side-folding blades actuated by said cam-wheel, the pivoted arms carried by the cross-head and means for tilting said arms as the cross-head reciprocates, an edge-folding blade secured to each of said arms, and a pivoted folding member carried by each arm, as set forth.

18. A wrapping-machine, comprising in combination with the frame, the driving-shaft, cam-wheel rotating therewith, horizontally-movable folding-blades and levers actuated by the cam-wheel for operating the same, a reciprocating cross-head, pivoted arms carried thereby, and adapted to be tilted as the cross-head reciprocates, edge-folding blades carried by said arms adapted to be thrown toward each other, as said arms approach their highest position, and means for holding said blades so that as they descend they will be held parallel to each other, and a pivoted folding member carried by each arm, as set forth.

19. A wrapping-machine, comprising in combination with the frame, the driving-shaft, cam-wheel rotating therewith, the horizontally-movable folding-blades, levers connected with said cam-wheel for operating said folding-blades, a reciprocating cross-head and connections between same and the cam-wheel, the pivoted arms carried by the cross-head, and rocked or tilted as said cross-head reciprocates, a blade carried by each of said arms, which blade is adapted to fold the opposite edges of the wrapper, and retaining guide-plates held to the frame of the machine behind which said edge-folding blades are adapted to engage, and to be held in parallel relation against the article to be wrapped as said blades are descending, and a pivoted folding-flap carried by each arm, as set forth.

20. A wrapping-machine, comprising in combination with the frame, the driving-shaft and cam-wheel rotating therewith, a reciprocating cross-head, the horizontally-movable folding-blades, the pivoted arms carried by the cross-head, a blade adapted to fold the opposite edges of the wrapper carried by each of said arms, means for throwing said edge-folding blades toward each other as the cross-head is driven to its highest position, stationary retaining guide-plates behind which said cross-head is thrown, a pivoted folding member on each of said arms and having a projection which is adapted to fold the top flaps slightly in advance of the folding of the edge flaps, and means for throwing said pivoted folding member outward, as the opposite edge flaps are folded, as set forth.

21. A wrapping-machine, comprising in combination with the frame, the driving-shaft and cam-wheel rotating therewith, the horizontally-movable folding-blades, means for actuating same, the reciprocating cross-head, pivoted arms carried thereby, and means for tilting the same as the cross-head reciprocates, folding-blades secured one to each arm, which blades are adapted to fold the opposite edges of the flap, one in advance of the other as said blades are held in parallel relation, and on their downward movement, a pivoted folding member on each of said arms, a stationary portion of the frame in the path of said pivoted folding member adapted to throw the latter outward as the opposite edge flaps are being folded, as set forth.

22. A wrapping-machine, comprising in combination with the frame, the operating-shaft and cam-wheel rotating therewith, the horizontally-movable folding-blades and means for operating the same, the cross-head, connections between same and the operating-shaft, the pivoted arms carried by the cross-head, means for tilting said arms as the cross-head reciprocates, the edge-folding blades and pivoted folding member carried by each of said arms, means for adjusting said edge and top folding members longitudinally on each of said arms, as set forth.

23. A wrapping-machine, comprising in combination with the frame, the operating-shaft, a reciprocating cross-head, pivoted arms carried by said cross-head, means for imparting an intermittent motion to the cross-head as the shaft is rotated.

24. A wrapping-machine, comprising in combination with the frame, the driving-shaft, a reciprocating cross-head, and means connected with said shaft for operating same, pivoted arms carried by said cross-head, and means for throwing the upper ends of said arms toward each other when the cross-head is at its upper end, and stationary, as set forth.

25. A wrapping-machine, comprising in combination with the frame, the driving-shaft, the cam-wheel, a reciprocating cross-head, the horizontal folding-blades, means for operating the same, a sliding plate carried by the cross-head, and having pin and lever connections with said cam-wheel, the pivoted arms, and means for actuating same as said plate slides, as set forth.

26. A wrapping-machine, comprising in combination with the frame, driving-shaft, cam-wheel rotating therewith, a reciprocating cross-head, a sliding plate secured to said cross-head, and having a longitudinal ply, pivoted arms carried by the cross-head, a pivoted and tilting link actuated by said sliding plate, and adapted to operate said pivoted arms as the cross-head and plate carried thereby are reciprocated.

27. A wrapping-machine, comprising in combination with the frame, the driving-shaft and cam-wheel rotating therewith, a reciprocating cross-head, a plate having a longitudinal sliding connection with said cross-head, pin and lever connections between said plate and the cam-wheel, the arms carried by the cross-head, and having their lower ends angled, one of said angled ends being connected to receive the convex end of the other, and adapted to tilt in contact with each other, and a link adapted to tilt one of said levers, as set forth.

28. A wrapping-machine, comprising in combination with the frame, the driving-shaft and cam-wheel rotating therewith, the reciprocating cross-head adapted in its stationary position for a moment when at its highest limit and sliding plate mounted thereon, pin and lever connections between said cam-wheel and the sliding plate, the arms carried by the cross-head and having their lower portions angled, one end being connected and the other convex, and held in contact with each other, a link mounted on one of the pivots of said arms, and having pivotal connection with the angled portion of one of said arms, whereby as said sliding plate is reciprocated independent of the cross-head, said arms are tilted upon their pivots, as set forth.

29. A wrapping-machine, comprising in combination with the frame, a driving-shaft, reciprocating cross-head, a sliding plate mounted thereon, connections between said sliding plate and the driving-shaft, the pivoted arms carried by the cross-head, and having their lower ends angled and turning in contact with each other, one of the meeting ends of said arms being connected to receive the convex end of the other, shoulders on said ends to limit the throw of said arms, a link carried on one of the pivots of said arms, and having pivotal connection with the angled portion of an arm, and in free end engaging a means in said sliding plate, as set forth.

30. In a wrapping-machine, the combination with the frame, the shaft, the reciprocating cross-head, the sliding plate having slots at its opposite ends, covers secured to the cross-head and passing through said slots to limit the throw of said plate, the arms pivoted at their angled portions to the cross-head, the inner ends of said arms, being held in frictional contact, shoulders to limit the throw of said arms, and dotted guide-plates through which the arms pass, a link mounted on one of the pivots of said arms and having pivotal connection with the angled end of one of said arms, the end of said link adapted to rest in a recess in said sliding plate, and to be tilted by the latter as the plate reciprocates independent of the cross-head, as set forth.

31. In a wrapping-machine, the combination with the frame, the

driving-shaft, the cam-wheel rotating therewith, the cross-head, the pivoted cross carried thereby, sliding plate mounted upon the cross-head, means for tilting said arms as the plate moves independent of the cross-head, a dotted lever *O* pivoted at one end to the frame of the machine, plunger connection between said lever and sliding plate, and a pin *C* mounted eccentrically on said cam-wheel and working in the slot of said lever, whereby the cross-head has an oscillated motion during its upward movement, and a gradual movement on the downward throw of said cross-head, as set forth.

22. A wrapping-machine, comprising in combination with the frame, the driving-shaft and cam-wheel rotating therewith, a reciprocating cross-head, sliding plate mounted thereon, pivoted arms carried by the cross-head and means for tilting said arms as said plate is actuated independent of the cross-head, a dotted lever pivoted to the stationary portion of the frame, a wrist-pin carried by the cam-wheel and having a sliding play in said lever, and plunger connection between said sliding plate and lever, as set forth.

23. A wrapping-machine, comprising in combination with the frame, the driving-shaft and cam-wheel rotating therewith, a segment-arm mounted on one face of the cam-wheel, the pivoted levers *L* and *V*, the folding-blades actuated by said levers *L* and *V*, the paper-guiding plate mounted on the table, a pivoted lever *K* actuated by said lever *L* for reciprocating said guide-plate.

24. A wrapping-machine, comprising in combination with the frame, driving-shaft, the cam-wheel rotating therewith, the lever *V* normally held in contact with the cam edge of said wheel, a horizontal folding-blade having a bar *V* engaging an aperture in the upper end of said lever, a spring *V* adapted to said bar and a pin *V* secured to the free end of said spring, and secured to slide in diagonally-disposed slot *V* in the frame of the machine, whereby as said horizontal blade is drawn forward, the spring will be slightly under tension, and the folding-blade adapted to yield slightly, as set forth.

25. A wrapping-machine, comprising in combination with the frame, the driving-shaft and cam-wheel rotating therewith, a segment-arm on the face of said cam-wheel, the pivoted lever *L* actuated by said segment-arm, a spring mounted on the pivoted pin of said lever, one end bearing against the stationary part of the frame, its other end against a pin on said lever, and adapted to normally hold the lower curved portion of said lever in the path of the circumference of said segment-arm, a pin carried at the upper end of said lever, the folding-blade secured to said pin and a spring secured to said blade, and a tilting lever dotted, and engaging said pin, and a paper-guide plate actuated by said tilting lever, as set forth.

26. In a wrapping-machine, the combination with the frame, the driving-shaft, the cam-wheel, a reciprocating cross-head, a sliding plate mounted on said cross-head, pivoted connections between the cam-wheel and said plate, and a spring bearing against the cross-head and adapted to flexibly engage and hold the same expanded while said plate has a movement independent of the cross-head, as set forth.

27. A wrapping-machine, comprising in combination with the frame, the driving-shaft, the cam-wheel rotating therewith, the segment-arm, the pin mounted on said segment, the tilting lever actuated by the segment-arm, and the folding-blade actuated by said lever, a plunger, a spring-actuated pivoted lever having connection with said plunger, a trip member pivoted to the frame and having flat connections with said plunger engaging lever, the lower end of said trip disposed in the path of said pin on the segment-arm, whereby the plunger is drawn forward and automatically returned to its starting position by said spring-actuated lever, as set forth.

28. A wrapping-machine, comprising in combination with the frame, the driving-shaft and cam-wheel, the plunger, the table on which the same is mounted, the spring-actuated lever engaging said plunger, the pivoted trip, flat connection between the same and said lever, the pin mounted on the cam-wheel adapted to contact with said trip to drive the plunger forward, said plunger being longitudinally slotted, a spring secured to the frame and having its lower free end engaging in the slotted end of said plunger, as set forth.

29. A wrapping-machine, having in combination with the frame, the driving-shaft, the cam-wheel rotating therewith, the plunger and folding means, and mechanism for operating the same, the folding-table having diagonally-disposed and slightly-curved slots in its opposite edges, one in advance of the other, and into which the last flaps of the wrapper are adapted to engage as the articles being wrapped are successively driven by the plunger outward, the outer marginal walls of said slots projecting outward over the opposite sides of the table, forming wings to guide the end flap, as set forth.

30. In combination with the cross-head and pivoted arms carried thereby, the folding-blade secured to each arm, said plate having its lower end slotted, one edge of which is provided with an abrupt curved portion *T*, and its opposite edge curved gradually, as set forth.

699,751. SUPERPOSED TURRET. THOMAS C. FURRY, U. S. Navy. Filed May 24, 1901. Serial No. 61,706. (No model.)

Claim.—1. The combination with a pair of turrets arranged one above the other, of independent means for rotating each turret separately, substantially as described.

2. The combination with a pair of turrets arranged one above the other, of independent means for rotating each turret separately, and means for locking said turrets together when desired, substantially as described.

3. The combination with a pair of turrets arranged one above the other, of independent means for rotating each turret separately, means for locking said turrets together when desired, and means for throwing the motive power of either turret out of action, substantially as described.

4. In a vessel, the combination with a supporting-platform, a lower turret revolvably mounted thereon, and means for rotating said turret, of an upper turret revolvably mounted above the lower turret, and independent means for rotating said upper turret independently of said lower turret, substantially as described.

5. In a vessel, the combination with a supporting-platform, a lower turret revolvably mounted thereon, and means for rotating said turret, of an upper turret revolvably mounted above the lower turret, and independent means for rotating said upper turret independently of said lower turret, with means for locking the two turrets together when desired, substantially as described.

6. In a vessel, the combination with a supporting-platform, a lower turret revolvably mounted thereon, and means for rotating said turret, of an upper turret revolvably mounted above the lower turret, independent means for rotating said upper turret, with means for locking the two turrets together when desired, and means for throwing the mechanism for turning either turret out of action, substantially as described.

7. In a vessel, the combination with a supporting-platform, a lower turret revolvably mounted thereon, and a rack and pinion, with means for rotating said pinion, for rotating said turret, of an upper turret revolvably mounted above the lower turret, and independent means for rotating said upper turret, substantially as described.

8. In a vessel, the combination with a supporting-platform, a lower turret revolvably mounted thereon, and a rack and pinion, with means for rotating said pinion, for rotating said turret, of an upper turret revolvably mounted above the lower turret, and independent means for rotating said upper turret, with means for locking the two turrets together when desired, substantially as described.

9. In a vessel, the combination with a supporting-platform, a lower turret revolvably mounted thereon, and a rack and pinion with means for rotating said pinion, for rotating said turret, of an upper turret revolvably mounted above the lower turret, with means for locking the two turrets

together when desired, and means for throwing the mechanism for turning either turret out of action, substantially as described.

10. In a vessel, the combination with a supporting-platform, a lower turret revolvably mounted thereon, and means for rotating said turret, of an upper turret mounted above the lower turret, a tube rigidly connected to said upper turret and projecting downward through said lower turret, and means for rotating said tube, substantially as described.

11. In a vessel, the combination with a supporting-platform, a lower turret revolvably mounted thereon, and means for rotating said turret, of an upper turret mounted above the lower turret, a tube rigidly connected to said upper turret and projecting downward through said lower turret, means for rotating said tube, means for locking the two turrets together when desired, and means for throwing the mechanism for turning either turret out of action, substantially as described.

12. In a vessel, the combination with a supporting-platform, a lower turret revolvably mounted thereon, and means for rotating said turret, of an upper turret mounted above the lower turret, a tube rigidly connected to said upper turret and projecting downward through said lower turret, means for rotating said tube, means for locking the two turrets together when desired, and means for throwing the mechanism for turning either turret out of action, substantially as described.

13. In a vessel, the combination with a supporting-platform, a lower turret revolvably mounted thereon, and means for rotating said turret, of an upper turret mounted above the lower turret, a tube rigidly connected to said upper turret and projecting downward through said lower turret, apparatus for applying connection to the upper turret mounted in said tube, and means for rotating said tube, substantially as described.

14. In a vessel, the combination with a supporting-platform, a lower turret revolvably mounted thereon, and means for rotating said turret, of an upper turret mounted above the lower turret, a tube rigidly connected to said upper turret and projecting downward through said lower turret, means for rotating said tube, apparatus for applying connection to the upper turret mounted in said tube, and means for locking the two turrets together when desired, substantially as described.

15. In a vessel, the combination with a supporting-platform, a lower turret revolvably mounted thereon, and means for rotating said turret, of an upper turret mounted above the lower turret, a tube rigidly connected to said upper turret and projecting downward through said lower turret, apparatus for applying connection to the upper turret mounted in said tube, means for rotating said tube, means for locking the two turrets together when desired, and means for throwing out of action the mechanism for turning either turret, substantially as described.

16. In a vessel, the combination with a supporting-platform, a lower turret revolvably mounted thereon, and means for rotating said turret, of an upper turret mounted above the lower turret, a tube rigidly connected to said upper turret and projecting downward through said lower turret, anti-friction-bearings at the base of said tube for supporting the upper turret, and means for rotating said tube, substantially as described.

17. In a vessel, the combination with a supporting-platform, a lower turret revolvably mounted thereon, and means for rotating said turret, of an upper turret mounted above the lower turret, a tube rigidly connected to said upper turret and projecting downward through said lower turret, anti-friction-bearings at the base of said tube for supporting the upper turret, means for rotating said tube, and means for locking the two turrets together when desired, substantially as described.

18. In a vessel, the combination with a supporting-platform, a lower turret revolvably mounted thereon, and means for rotating said turret, of an upper turret mounted above the lower turret, a tube rigidly connected to said upper turret and projecting downward through said lower turret, roller-bearings at the base of said tube for supporting the upper turret, means for rotating said tube, means for locking the two turrets together when desired, and means for throwing out of action the mechanism for turning either turret, substantially as described.

699,752. HOOK. AUGUST GARNER, Owner Inventor, of Costa Rica. Filed Nov. 6, 1901. Serial No. 61,800. (No model.)

Claim.—The method of making a hook from wood bark, which consists in flattening the bark to remove the contained gum, then, while

one wet, cutting the bark into strips of a width equal to the length of the bark-body and then subjecting the strips to suitable molding machinery to split or divide the bark into flaps or blades.

699,753. LINCOLN-PRESS. HENRY W. GOSWELL, Stationer, England. Filed Feb. 27, 1901. Serial No. 61,800. (No model.)

Claim.—1. The combination of a continuously-rotating drum, a frame oscillating upon it, a plate carried by the frame, and means for pressing the plate intermittently against the drum.

2. The combination of a continuously-rotating drum, a frame oscillating upon it, plates carried by the frame, means for pressing the plates intermittently against the drum, and apparatus connecting the plates so that they move in and out together.

3. The combination of a continuously-rotating drum, a frame oscillating upon it, plates carried by the frame, means for pressing the plates intermittently against the drum, a rocking lever pivoted on the frame and bearing against one plate, and a link connecting the lever to the other plate.

4. The combination of a continuously-rotating drum, a frame oscillating upon it, plates carried by the frame, hydraulic pressure on the frame acting on the plates, and means for intermittently admitting water to the pressure.

5. The combination of a continuously-rotating drum, a frame oscillating upon it, plates carried by the frame, hydraulic pressure on the frame acting on the plates, a valve for the pressure, and means for automatically operating the valve by the movements of the frame.

6. The combination of a continuously-rotating drum, a frame oscillating upon it, plates carried by the frame, hydraulic pressure on the frame acting on the plates, a valve for the pressure carried by the oscillating frame, and means carried by the stationary framing for operating the valve.

7. The combination of an oscillating press, a valve moving with the press, a valve-stem operating the valve, a disk on the stem, a stud on the disk, and a spring-arm turning on a stationary pivot and adapted to engage the stud.

8. The combination of an oscillating press, in inlet and an exhaust valve moving with the press, valve-stems operating the valves, plates on the stems working with one another, studs on the plates, and a spring-arm turning on a stationary pivot and adapted to engage the studs.

9. The combination of an oscillating press, in inlet and an exhaust valve moving with the press, valve-stems operating the valves, plates on the stems working with one another, studs on the plates, a pair of arms turning on stationary pivots, a spring connecting the arms, and stationary stops for the arms.

699,754. GUM-PLANTER. LOUIS GRAMER, Inventor, U. S. Filed Feb. 28, 1901. Serial No. 61,800. (No model.)

Claim.—1. In dropping mechanism for condenser, the combination of a dropping-plate having a coal-receiving cell, a barrier on one side of the cell, and a feeder-plate on the opposite side of the cell movable toward and from the barrier and the intervening cell.

2. In dropping mechanism for condenser, the combination of a dropping-plate having a coal-receiving cell, a barrier on one side of the cell, and a barrel-edge feeder-plate on the opposite side of the cell, movable toward and from the barrier and the intervening cell.

3. In dropping mechanism for condenser, the combination of a coal-wheel having a coal-receiving cell, a barrier on one side of the cell, and

a feeder on the opposite side of the cell movable radially of the wheel toward and from the barrier and the intervening cell.

4. In dropping mechanism for seedlings, the combination of a rotatable seed-wheel having a seed-receiving cell, a stationary barrier alongside one side of the path of motion of the cell, and a feeder on the opposite side of the cell movable toward and from the cell and rotating with the wheel; the movement of the feeder being so timed that the nearest approach of the feeder to the cell occurs when the cell is adjacent to the barrier.

5. Dropping mechanism for seedlings, comprising a seed-wheel having cells, a feeder-disk journaled above the seed-wheel concentric with the path of motion of the cells, and a barrier alongside the cells, opposite the nearest approach of the feeder-disk to the cells.

6. Dropping mechanism for seedlings, comprising a seed-wheel having cells, a level-edge disk pivoted above the seed-wheel inside the path of motion of the cells and concentric with each path, and a barrier outside the cells, opposite the nearest approach of the disk to the cells.

7. Dropping mechanism for seedlings, comprising a seed-wheel having cells, a disk journaled above the seed-wheel inside the path of motion of the cells and concentric therewith, means for rotating the disk in the same direction as the motion of the wheel, and a barrier outside the cells opposite the nearest approach of the disk to the cells.

8. Dropping mechanism for seedlings, comprising a seed-wheel having cells, a level-edge disk with an unbroken perimeter pivoted above the seed-wheel concentric therewith, and means, covered by the disk, for transmitting motion from the seed-wheel to the disk.

9. Dropping mechanism for seedlings, comprising a seed-wheel having cells, a feeder-disk pivoted above the seed-wheel concentric therewith, and a radially-adjustable connection between the under side of the disk and the upper side of the wheel, such connection being cutaway covered by the disk.

10. Dropping mechanism for seedlings, comprising a seed-wheel having cells, a disk journaled above the seed-wheel concentric therewith, a radial rib on the under side of the disk and a stud projecting upward from the wheel into engagement with the rib.

11. Dropping mechanism for seedlings comprising a box-bottom having a discharge-opening, a seed-wheel having cells adapted to discharge through the opening in the bottom of the box, and a feeder-plate approaching the cells and receding therefrom at a point non-coincident with the discharge-opening of the seedlings.

12. Dropping mechanism for seedlings comprising a seed-wheel having cells, a feeder-disk smaller than the circle described by the cells and pivoted concentric with each circle, and a cut-off in the wide space formed by the eccentricity of the disk.

899,755. TRAIN-ORDER BOX IN CONNECTION WITH SIGNAL-PRINTER. ISA S. BROWN, Los Angeles, Cal. Filed Mar. 4, 1905. Serial No. 97,894. (No model.)

Claim.—1. The combination is a gravity-operated camshaft of the camshaft-arm operatively connected with the operating-lever with a stationary train-order box having a swinging cover adapted to be swung open and uncover the box only after the operating-lever is shown in the danger position and means substantially as shown to prevent the movement of the lever to a clear position until after the cover is closed.

2. In a gravity-operated camshaft system, in which the camshaft-arm are operated by levers in the office of the local operator, a train-order box, having a swinging cover arranged to prevent the use of the box when the cover is closed, means to hold the cover closed and prevent it being opened until after the operating-lever is thrown to the danger position, carrying the camshaft-arm to the same position, means to hold said lever in said danger position until after the box is closed.

3. In a gravity-operated camshaft system, the combination with

the camshaft-arm operatively connected with an operating-lever of a stationary train-order box, the said box being provided with a swinging cover, a locking-bar hinged to the side of the box and arranged when closed to lay upon the cover and prevent the cover from being opened when the bar is in a closed position, the bottom of the said locking-bar adapted to contact with the operating-lever when out of a danger position and be prevented thereby from being opened except when the bar is in a clear position, the said locking-bar being provided with a shoulder therein to engage the operating-lever when the locking-bar is in the open position and prevent the lever from moving from that position while in the open position, the said locking-bar adapted to contact with the edge of the cover while the cover is open and be thereby prevented from being closed while the cover is in the open position as shown.

4. The combination is a camshaft system of the stationary train-order box C having swinging cover K provided with the front end R the locking-bar L, hinged to the side of the box and having shoulder P to engage the edge of the cover and thereby prevent the cover from accidental closing, the locking-bar being also provided with the lever-engaging shoulder L' to hold the lever in the danger position while the locking-bar is open, the locking-bar hinged adjacent to the lever and adapted to block the path of the lever and prevent the movement of the lever while the locking-bar is open, but to permit the free movement of the lever when the locking-bar is closed.

5. A stationary train-order box having a swinging cover arranged to prevent the use of the box when closed, and a swinging locking-bar hinged thereon adapted to hold the cover shut when the bar is closed, in combination with an operating-lever operatively connected with a camshaft-arm, the lever arranged to swing in a path and prevent the locking-bar from being opened when the lever is out of the danger position, and the bar, being provided with a shoulder to engage and hold the lever in the danger position when the bar is open, the locking-bar arranged to contact with the cover when the cover is open and be prevented thereby from closing while the cover is open.

899,756. WHEEL. CHARLES L. BRADY, Brooklyn, N. Y., assignor to Burtis H. Williams, New York, N. Y. Filed Mar. 30, 1907. Serial No. 629,946. (No model.)

Claim.—1. In a wheel, the combination with its hub and spokes, of a homogeneous fully comprising laminae suitably joined together and provided with an interior chamber between each lamina, and a suitable disc around each fully.

2. In a wheel, the combination with its hub and spokes, of a fully comprising laminae suitably joined together and containing a pocket closed

to the atmosphere, one of the laminae, where it faces an adjoining lamina being provided with a depression for the purpose of forming such pocket.

3. In a wheel the combination with its hub and spokes, of a fully comprising laminae suitably joined together and containing a pocket, one of the interior laminae where it faces adjoining laminae being perforated for the purpose of forming such pocket.

4. In a wheel, the combination with its hub and spokes, of a fully comprising laminae suitably joined together and containing a pocket, one of the interior laminae being perforated and an adjoining lamina where it faces each perforation being provided with a depression on its face, whereby such pocket is formed.

5. In a wheel, the combination with its hub and spokes, of a fully comprising a series of laminae including internal chambers between interior surfaces of each lamina and disposed symmetrically around each fully.

6. In a wheel, the combination with its hub and spokes, of a fully comprising laminae suitably joined together, each lamina sloping toward each other and toward the central vertical plane of the wheel and being joined together at both sides of said plane.

7. In a wheel, the combination with its hub and spokes, of a fully comprising two groups of laminae sloping toward each other and toward the central vertical plane of the wheel and other laminae secured to laminae in both of said groups.

8. In a wheel, the combination with its hub and spokes, of a fully comprising interior pockets provided at both sides of its central vertical plane, each fully being made solid along each plane.

9. In a wheel, the combination with its hub and spokes, of a fully comprising a series of laminae, tension-rods passing through each fully, and means for increasing the tension of each rod independent of the tension of the portions of the spokes between fully and hub.

10. In a wheel, the combination with its hub and spokes, of a spoke passing through the fully, each spoke being deflected near the point where it enters the fully and a head insulating portions of the spokes at both sides of the point of deflection.

11. In a wheel, the combination with its hub, of a fully comprising laminae suitably joined together, spokes passing through the same, and elastic packings around the spokes and extending into adjoining laminae.

12. In a wheel, the combination with its hub, of a fully comprising laminae suitably joined together, spokes passing through the same and elastic packings around the spokes and extending into adjoining laminae.

13. In a wheel, the combination with its hub, of a fully comprising laminae suitably joined together, spokes passing through the same and elastic packings around the spokes and extending into adjoining laminae.

14. In a wheel, the combination with its hub, of a fully comprising a U-shaped rod having its ends extend into the body of the fully and a disc secured to said rod and to the outer surface of the fully.

15. In a wheel, the combination with its hub and spokes, of a fully comprising laminae suitably joined together, and a disc along the outer surface of the fully and extending over the joints between the laminae and along the bearing portion of the wheel.

899,757. CHILD'S TEETHING-SIPPLE. WILLIAM HOWELL, Brooklyn, N. Y. Filed Sept. 4, 1904. Serial No. 74,088. (No model.)

Claim.—1. In a device of the character described, the combination with a guard comprising a centrally-apertured frusto-conical disk, having an annular groove in the wall of said aperture intermediate the base and apex of said disk, a nipple provided on the end of its neck with an annular bead or flange, said neck and flange being respectively fitted in the said aperture and groove, and a handle and holder provided at one end with a transverse flange within the said aperture and the neck of the nipple, and operating to hold said neck and flange to their seats in the disk, said transverse flange being provided for a portion of its length and engaging a correspondingly-shouldered portion of the wall of the said aperture, substantially as described.

2. In a device of the character described, the combination with a guard comprising a centrally-apertured frusto-conical disk, having an annular groove in the wall of said aperture intermediate the ends of the handle, a holder and handle provided at one end with a transverse flange for a portion of its length and provided with a rounded and unrounded end, a

sipple provided on the end of its neck with an annular bead or flange, said neck and flange being respectively fitted in the said aperture and groove, the unrounded end of the transverse flange being fitted in the end of said neck and operating to hold the latter and the flange to their seats in the disk, and the threaded portion of said transverse flange engaging a correspondingly-threaded portion formed in the wall of the said aperture, said handle and holder being provided with a longitudinal duct or channel extending centrally through the same and through the transverse flange, substantially as described.

899,758. COMBINED COTTON-PLANTER AND FERTILIZER-DISTRIBUTOR. FRANKLIN M. HUGHES, Vicksburg, Miss., assignor of one-half to Ernest L. Hahmy and Miss Rodgers, Vicksburg, Miss., Co. Filed Sept. 24, 1904. Serial No. 70,028. (No model.)

Claim.—1. In a combined planter and fertilizer-distributor, the combination of a hopper having seed and fertilizer compartments with discharge-openings in the lower side thereof, laterally-movable cut-off plates under the bottom of the hopper and having each an outwardly-extending arm, a rearwardly-extending operating-arm, pivoted at its front end under the bottom of the hopper, connected to the arm of the cut-off plate to adjust the latter and having a transverse slotted portion at its rear end and a cut-screw engaging said slotted transverse rear portion of the operating-arm, a furrow-opener standard, a pair of laterally and oppositely inclined seed and fertilizer spouts having their upper ends under said openings in the hopper and their lower ends disposed in the same vertical plane, said fertilizer-spout being in the rear side of the furrow-opener standard, extending downwardly thereon and discharging immediately behind and at the lower end of the same, so that the fertilizer will be covered in the bottom of the furrow, and said seed-spout having its discharge end at some distance in rear of and at a higher plane than that of the fertilizer-spout so that the seed will be dropped on the loose soil which covers the fertilizer in the furrow and kept out of contact with and above the fertilizer, for the purpose set forth, substantially as described.

2. In a planter, the combination of a hopper having a discharge-opening in its lower side, a laterally-movable cut-off plate under the bottom of the hopper and having an outwardly-extending arm, a rearwardly-extending operating-arm pivoted at its front end under the bottom of the hopper, connected to the arm of the cut-off plate to adjust the latter, and having a transverse, slotted portion at its rear end, and a cut-screw engaging said slotted transverse rear portion of the operating-arm, substantially as described.

899,759. METALLURGICAL FURNACE. JOHN A. BRYAN, Philadelphia, Pa. Filed Aug. 9, 1903. Renewed Oct. 10, 1904. Serial No. 72,948. (No model.)

Claim.—1. A metallurgical furnace having a working chamber, a fire beneath the floor of the same, a discharge-flue communicating with said lower flue, and a discharge opening at that end of the working cham-

ber, through which said working chamber communicates with the discharge-flue, and means for applying heat independently to the working chamber and the base-flue, substantially as specified.

2. A metallurgical furnace having a working chamber, a flue beneath the floor of the same, a rear flue communicating with said base-flue, and a dampened opening at that end of the working chamber, through which said working chamber communicates with the rear flue, a return-flue over the top arch or crown of the working chamber, and means for applying heat independently to the working chamber and base-flue, substantially as specified.

3. A metallurgical furnace having a working chamber with bottom provided with ribs or projections for the support of the material to be treated, means for heating said material by gaseous products of combustion introduced into the working chamber, and provision for introducing a fluid treating agent into said working chamber, independently of the gaseous products of combustion, substantially as specified.

4. A metallurgical furnace having a working chamber, combined with means for introducing gaseous products of combustion into the same and a floor composed of blocks having therein channels or passages for conveying a fluid treating agent into the furnace independently of the gaseous products of combustion, substantially as specified.

5. A metallurgical furnace combined with means for introducing gaseous products of combustion into the same and having a floor composed of blocks with recessed upper faces, and channels or passages communicating with said recessed faces of the blocks and providing for the introduction of a fluid treating agent into the furnace, independently of the gaseous products of combustion, substantially as specified.

699,760. CHAIN-MAKING MACHINE. WILSON L. JONES, Chicago, Ill. Filed June 28, 1901. Serial No. 63,466. (No model.)

Claim.—1. In a machine adapted to form a chain from hooks and link-forming elements, the combination with means for holding the hooks longitudinally spaced, of means for applying the link-forming elements to the pair of positioned hooks while longitudinally spaced.

2. In a machine adapted to form a chain from hooks and link-forming elements, the combination with means for holding the hooks longitudinally spaced, of means for feeding the prongs of the staples into eyes of the pair of positioned hooks, while longitudinally spaced, and means for clamping the ends of the said staples to complete the links.

3. In a machine adapted to form a chain from hooks and link-forming elements, the combination with means for intermittently feeding the hooks and holding the same properly spaced, of means for intermittently feeding the staples into eyes of the pair of positioned and longitudinally spaced hooks, and means for clamping the ends of the inserted staples to complete the links.

4. In a machine adapted to form a chain from hooks and link-forming staples, the combination with means for feeding the hooks and holding the same longitudinally spaced, of a supply-holder for the staples, a reciprocating feed-plunger cooperating with the delivery end of said holder to feed the staples, one at a time, into eyes of the pair of positioned and

longitudinally spaced hooks, and means for clamping the ends of the inserted staples to complete the links.

5. In a machine adapted to form a chain from hooks and link-forming staples, the combination with means for intermittently feeding the hooks and holding the same longitudinally spaced, of a supply-holder for the staples, a reciprocating feed-plunger cooperating with the delivery end of the said holder to feed the staples, one at a time, into eyes of the pair of positioned and longitudinally spaced hooks, and means for clamping the ends of the inserted staples to complete the links.

6. In a machine adapted to form a chain from hooks and link-forming staples, the combination with means for feeding the hooks and holding the same longitudinally spaced, of means for feeding the staples into eyes of the pair of positioned and longitudinally spaced hooks, a pair of clamping-placers for partly clamping the ends of the inserted staples and a pair of cooperating clamping-disks for completing the links.

7. In a machine adapted to form a chain from hooks and link-forming staples, the combination with means for intermittently feeding the hooks and holding the same properly spaced, of a supply-holder for the staples, a reciprocating feed-plunger cooperating with the delivery end of the said holder to feed the staples, one at a time, into eyes of a pair of positioned hooks, a pair of clamping-placers for partly clamping the ends of the inserted staples, and a pair of cooperating clamping-disks for completing the links.

8. In a machine adapted to form a chain from hooks and link-forming staples, the combination with means for intermittently feeding the hooks and holding the same properly spaced, of a supply-holder for the staples, a pair of reversibly-reciprocating slides, a feed-plunger on one of said slides cooperating with the delivery end of said holder to feed the staples, one at a time, into eyes of a pair of positioned hooks, a pair of plungers carried by the other slide and operating to partially clamp the ends of the inserted staples, and a pair of cooperating clamping-disks carried, one by each slide, and operating to complete the links.

9. In a machine adapted to form a chain from hooks and link-forming staples, the combination with means for intermittently feeding the hooks and holding the same properly spaced, of a supply-holder for the link-forming staples, a pair of reversibly-reciprocating slides, a feed-plunger on one of said slides cooperating with the delivery end of said holder to feed the staples, one at a time, into eyes of a pair of positioned hooks, a pair of plungers pivoted to one of said slides and operating to partially clamp the ends of the inserted staples, a plunger-operating cam-plate movable first with and then with respect to the plunger-carrying slide, a pair of clamping-disks carried one by each slide and operating to complete the links, and automatic means for moving the said parts with properly-timed action.

10. In a machine adapted to form a chain from hooks and link-forming staples, the combination with a feed-curve for feeding and holding the hooks longitudinally spaced, of means for applying the link-forming elements to the pair of positioned and longitudinally spaced hooks.

11. In a machine adapted to form a chain from hooks and link-forming elements, the combination with a feed-curve for feeding and holding the hooks longitudinally spaced, of means for holding the said hooks subject to said curve, and means to move in a series extending in longitudinal line, parallel to said curve, and means for applying the link-forming elements to the pair of positioned and longitudinally spaced hooks.

12. In a machine adapted to form a chain from hooks and link-forming staples, the combination with an intermittently-movable feed-curve, for feeding and holding the hooks in a longitudinally-spaced series, of means for feeding the prongs of the link-forming staples into eyes of the pair of positioned and longitudinally spaced hooks, and means for clamping the ends of the inserted staples to complete the links.

13. In a machine adapted to form a chain from hooks and link-forming staples, the combination with an intermittently-movable feed-curve and cooperating guide-channel for guiding and feeding the hooks in a longitudinally-spaced series, of a staple-supply holder, a reciprocating feed-plunger cooperating with the delivery end of said holder to feed the staples, one at a time, into eyes of a pair of positioned hooks, and means for clamping the ends of the inserted staples to complete the links.

14. In a machine adapted to form a chain from hooks and link-forming elements, the combination with a feeding device serving to hold the hooks properly spaced, of a plurality of magazines for the hooks, a rotary magazine-holder, and guide opening to deliver said magazines to said holder, at one side thereof, which holder is operated by the over-riding-weight of said magazines and automatically delivers the hooks to said feed device.

15. In a machine adapted to form a chain from hooks and link-forming elements, the combination with a hook-feed device serving to hold the hooks properly spaced, of a magazine for the hooks, means for moving said magazines into a position to deliver said hooks to said feed device, and means for applying the link-forming elements to the hooks.

16. In a machine adapted to form a chain from hooks and link-form-

ing elements, the combination with a hook-feeding device serving to hold the hooks properly spaced, of a magazine for holding and opening the hooks in an aligned series, a rotary magazine-holder operating to move said magazine transversely of the line of feed, into a position to deliver said hooks to said feeding device, and means for applying the link-forming elements to said hooks while the hooks are subject to said feeding device.

17. In a machine adapted to form a chain from hooks and link-forming elements, the combination with a hook-feeding device serving to hold the hooks properly spaced, of a magazine for holding and opening the hooks in an aligned series, a stop-bar extending longitudinally of said feed device, a rotary magazine-holder operating to move said magazine transversely of the line of feed and to deliver the hooks to said feed device and against said stop-bar, and means for applying the link-forming elements to the hooks while they are subject to said feed device.

18. In a machine adapted to form a chain from hooks and link-forming elements, the combination with a feeding device serving to hold the hooks properly spaced, of a magazine for holding and opening the hooks in an aligned series, a stop-bar extending in the line of feed, a rotary magazine-holder operating to move said magazine transversely of the line-feed and deliver the hooks to the said feed device and against said stop-bar, a grooved concave guide cooperating with said holder to deliver said hooks to said feed device, and means for applying the link-forming elements to the hooks while they are subject to said feed device.

19. In a machine adapted to form a chain from hooks and link-forming elements, the combination with an intermittently-movable feed-curve, of a magazine for holding and opening the hooks in an aligned series, means for moving said magazine transversely of the line of feed, and into position to deliver the hooks, properly spaced, to said feed-curve, and means for applying the link-forming elements to the hooks while they are subject to said feed-curve.

20. In a machine adapted to form a chain from hooks and link-forming elements, the combination with an intermittently-movable feed-curve, of a magazine for holding and opening the hooks in an aligned series, a stop-bar extending in the line of feed and into a position to deliver said hooks, properly spaced, to said feed-curve and against said stop-bar, and means for applying the link-forming elements to the hooks while they are subject to said feed-curve.

21. In a machine adapted to form a chain from hooks and link-forming elements, the combination with a hook-feeding device serving to hold the same properly spaced, of a magazine for holding and opening the hooks in an aligned series, a gravity-actuated holder for said magazine operating to move the same transversely of the line of feed and to deliver the said hooks, properly spaced, to said feeding device and means for applying the link-forming elements to the said hooks while they are subject to said feeding device.

22. In a machine adapted to form a chain from hooks and link-forming elements, the combination with a feed-curve serving to hold the hooks properly spaced, of a stop-bar extending longitudinally of said feed-curve, a magazine for holding and opening the hooks in an aligned series, a gravity-actuated rotary magazine-holder operating to move said magazine laterally and to deliver the hooks to said feed-curve, properly spaced, and against said stop-bar, and with the magazine clear of said stop-bar, whereby a continuous supply of loaded magazines is effected.

23. In a machine adapted to form a chain from hooks and link-forming staples, the combination with means for holding the hooks in a longitudinally-spaced series, of means for feeding the staples into the eyes of different longitudinally-spaced hooks and clamping the ends of the same, one or more opening-blades, and means for intermittently moving said opening-blades between the assembled hooks, for cooperative with the clamping means.

24. In a machine adapted to form a chain from hooks and link-forming staples, the combination with means for holding the hooks spaced, of means for feeding the staples into eyes of the positioned hooks and clamping the ends of the same, and one or more blades movable between the assembled hooks for successively holding and lowering the accurate spacing of the hooks.

25. In a machine adapted to form a chain from hooks and link-forming staples, the combination with means for intermittently feeding the staples into eyes of the positioned hooks, means for clamping the ends of the inserted staples, and a plurality of opening-blades intermittently movable between the assembled hooks, for lowering accurate spacing of the hooks, and at least one, thereof, serving as a former or mold for cooperating with the clamping means.

26. In a machine adapted to form a chain from hooks and link-forming staples, the combination with means for intermittently feeding the hooks and holding the same properly spaced, of means for feeding the staples into eyes of the positioned hooks, a pair of clamping-placers for partially clamping the ends of the inserted staples, a pair of cooperating clamping-disks for completing the links, a spacing-blade insertible between

the hooks in front of said placers, and a forming-blade insertible between the hooks, at a point between said clamping-disks.

27. In a machine adapted to form a chain from hooks and link-forming elements, the combination with means for feeding and holding the hooks in a longitudinally-spaced series, of means for intermittently applying the link-forming elements to the pair of positioned and longitudinally spaced hooks, and a cut-out device operating at predetermined intervals to cause a link-forming element to be omitted and the chain to be continued.

28. In a machine adapted to form a chain from hooks and link-forming elements, under a continuous action, the combination with a cut-out device operating, at predetermined intervals to cause a chain element to be omitted, which cut-out device involves a reversible, toothed ratchet member having a pair of reversing-steps, of a vibrating reversible driving-pawl cooperating with the teeth of said toothed ratchet member, and itself adapted to be reversed by the said reversing-step thereof.

29. In a machine adapted to form a chain from hooks and link-forming staples, the combination with means for intermittently feeding the hooks and holding the same in a longitudinally-spaced series, of a supply-holder for the staples, a reciprocating feed-plunger cooperating with the delivery end of said holder to feed the staples, one at a time, into eyes of the pair of positioned and longitudinally spaced hooks, and a cut-out device operating at predetermined intervals to interrupt the feed movement of said plunger and cause a staple to be omitted, thereby determining the length of the chain-section.

30. In a machine adapted to form a chain from hooks and link-forming staples, the combination with means for feeding the hooks and holding the same properly spaced, of a supply-holder for the staples, a staple-feeding device operating to intermittently feed the staples from said holder and apply the same to the hooks, and a cut-out device comprising a reversible ratchet member having a pair of spaced reversing-steps, a vibrating reversible driving-pawl cooperating with the teeth of said toothed member and itself reversed by the reversing-steps thereof, and a trip actuated by said reversible toothed member for causing said staple-feeding device to stop feed movements at predetermined intervals.

31. In a machine adapted to form a chain from hooks and link-forming staples, the combination with means for feeding and holding the hooks properly spaced, of a supply-holder for the link-forming staples, a reciprocating feed-plunger cooperating with the delivery end of said holder, to feed the staples, one at a time, into eyes of a pair of positioned hooks, a reciprocating driver for said feed-plunger, a lock normally connecting said feed-plunger to its driver, and a cut-out device for tripping said lock out of action at predetermined intervals, comprising a ratchet-disk with a lock-tripping pin or part, a pair of reversing-steps on said disk, and a vibrating arm provided with a pivoted reversible pawl having a pawl-reversing finger which works between and is acted upon by said reversing-steps.

32. In a machine adapted to form a chain from hooks and link-forming elements, under a continuous action, of a cut-out device operating, at predetermined intervals, to cause a chain element to be omitted, which cut-out device involves a reversible toothed ratchet member having a pair of reversing-steps, at least one of which steps is adjustable with respect to the other, to vary the length of the chain-section, and a vibrating reversible driving-pawl cooperating with the teeth of said toothed member and itself adapted to be reversed by the said reversing-step thereof.

699,761. INSULATOR. HENRY F. KREMER, St. Louis, Mo. Filed Jan. 27, 1902. Serial No. 91,465. (No model.)

Claim.—1. An insulator comprising a body portion, a circumferential groove located adjacent to one end thereof, parallel circumferential passages leading from said groove along the periphery of the body por-

tion, a depression formed in the face of the body portion for the reception of the electric conductor or rod, the groove being adapted to receive the loop of a suitable securing-wire, the ends of the latter being passed through the passages and folded over the rod, substantially as set forth.

2. An insulator comprising a body portion, an annular groove disposed adjacent to the base thereof, communicating passages leading from said groove at points diametrically opposite one another and opening at the face or top of the body portion, a depression formed in the face and disposed at right angles to a line connecting the passages aforesaid, a socket leading from the center of said depression, and a passage or perforation leading from the base of the socket for the reception of a securing-rod, substantially as set forth.

3. An insulator comprising a cylindrical body portion, an annular peripheral groove disposed adjacent to the base thereof, communicating passages leading from the groove, supplemental grooves formed in the face of the body portion leading from the passages aforesaid, a depression formed in the face and disposed at right angles to the supplemental grooves, a socket leading from the center of the depression, and a perforated passage leading from the socket for the reception of a securing-rod, substantially as set forth.

4. An insulator comprising a cylindrical body portion, an annular peripheral groove disposed adjacent to the base thereof, parallel diametrically separated passages leading from the groove and terminating at the face of the body portion, a depression disposed in the face of the body portion at right angles to the diametric line connecting said passages, and oblique perforations opening through the parallel passages, substantially as set forth.

699,762. DISINTEGRATING-MACHINE. JAMES M. MACDONALD, Detroit, Mich., assignor to Parke, Davis & Company, Detroit, Mich., a Corporation of Michigan. Filed May 12, 1901. Serial No. 69,009. (No model.)

Claim.—In a disintegrating-machine, the combination with a framework, of a conical grating therein provided with a continuous lateral flange or rim at its upper edge, said rim being rabbeted or recessed as described, a rectangular frame detachably arranged within said recessed rim, a conical blade detachably secured to the frame and resting upon the base of the grating, a rock-shaft within the grating, and cooperating blades carried by said rock-shaft, extending in proximity to the cleve.

699,763. REEL. GEORGE R. HATFIELD, Kalamazoo, Mich. Filed Oct. 25, 1901. Serial No. 79,000. (No model.)

Claim.—1. An attachment for a fish-reel consisting of the frame D with bearings for embracing one of the pillars of the reel; a coiled spring with adjusting-roller to be placed on the said pillar of the reel for applying regulated pressure to the frame D; side pieces D' on the said frame; cone-bearings F, F' with a screw-threaded connection between them for insertion through the perforations in the side pieces; and a roller, the ends of which are properly fitted to the cone-bearings and carried thereby in position to rest against the line wound upon the reel, all coacting substantially as described for the purpose specified.

2. An attachment for a fish-reel consisting of the frame D with bearings for embracing one of the pillars of the reel; side pieces D' on the said frame; cone-bearings F, F' with a screw-threaded connection between them for insertion through the perforations in the side pieces; and a roller, the ends of which are properly fitted to the cone-bearings and

carried thereby in position to rest against the line wound upon the reel, all coacting substantially as described for the purpose specified.

3. An attachment for a fish-reel consisting of a suitable frame rigidly connected to one of the pillars of the reel; a spring for applying pressure thereto; a roller carried by the said frame and adapted to rest against the line on the reel, coacting for the purpose specified.

4. The combination with a fish-line reel of a suitable frame having a roller adapted to rest against the line on the reel and a spring for exerting yielding pressure on the said frame.

5. The combination with a fish-line reel of a suitable frame having a roller adapted to rest against the line on the reel.

699,764. SYSTEM OF ARMATURE-WINDING FOR ELECTRIC MOTORS. THOMAS J. BERRY, Montreal, Canada. Filed Oct. 17, 1901. Serial No. 79,001. (No model.)

Claim.—In a system of armature-winding the combination of coils A' B' of the portion D' F' and B' being arranged to lie outside of coil A' between C' E' and portion between C' E' and A' to lie outside D' F' as shown and described.

699,765. METHOD OF CANNING CORN OR OTHER VEGETABLES. CLARENCE E. PLENNER and FRANK T. STARR, Waukegan, Wis. Filed Feb. 7, 1901. Serial No. 42,301. (No specimens.)

Claim.—1. The method of canning corn and other vegetables, consisting in, first, cooking the corn and raising the temperature thereof to a point considerably in excess of the normal boiling-point; second, filling the cans with corn at such temperature, under a surrounding atmospheric pressure greater than the normal pressure of the atmosphere, and sufficient to prevent the oblation of the contents of the cans; and third, sealing the cans while the contents are maintained at such temperature, and with the cans and contents subjected to such surrounding pressure.

2. The method of canning corn, and other vegetables, consisting in filling and sealing cans at a temperature in excess of the normal boiling-point, and simultaneously subjecting the cans and contents to a surrounding atmospheric pressure sufficiently in excess of the normal pressure, to prevent oblation.

3. The method of canning corn, and other vegetables, consisting in, first, cooking the vegetables; second, in filling the cans; and third, in sealing the cans, all of said steps being performed under a surrounding atmospheric pressure greater than normal.

4. The method of canning corn, or other vegetables, consisting, first,

In cooking the material and raising the temperature thereof materially above the normal boiling-point; second, filling the cans with material, at said temperature, and discontinuously applying an external air-pressure thereto sufficient to balance the internal steam-pressure of the material; and third, sealing the cans while such pressure is maintained.

699,766. WASHING-MACHINE. EMERY A. HANCOCK, Port Huron, Mich. Filed Aug. 25, 1904. Serial No. 72,902. (No model.)

Claim.—In a washing-machine, the combination with the end-receptacle, of a drive-shaft journaled in bearings above said receptacle, cranks upon the shaft arranged in angular relation to each other for the purpose set forth, power-rods carried by the cranks and extending from the latter within the receptacle, power-rods secured to the lower ends of the rods, guides for said rods, and a spring-biased packing in each guide.

699,767. FOCUSING ATTACHMENT FOR CAMERAS. FRANK W. SAKSE, Liverpool, England. Filed Oct. 7, 1900. Serial No. 72,912. (No model.)

Claim.—1. The combination with a photographic camera of a short-focus reversing-glass, and a carrier, connecting the back of the camera and the glass, and supporting the same substantially as set forth.

2. In combination with camera, a short-focusing reversing eyepiece and an adjustable carrier between the same and the back of the camera, substantially as described.

699,768. BOOT OR SHOE HEEL. FRANKLIN C. SAYLER, Frank-
lin, Mass., assignor to Walter E. Andrews, Boston, Mass. Filed Feb.
21, 1904. Serial No. 42,335. (No model.)

Claim.—A heel comprising a perforated leather top, a narrow rib of leather secured to the upper side of the top across the front part thereof forming a solid leather foot to the heel, a washer-plate secured to the upper side of the top in the rear of said narrow leather rib, a rubber core which covers the upper side of said top rearward of the narrow leather rib, a channel in said core to receive the said washer and having a projection or protrusion which extends through the perforated top, perforations in the washer and rubber to admit passage of air to covering the heel to the

bottom of a boot or shoe, and larger perforations in the top to receive the heads of the nails against the washer, substantially as described.

699,769. STREET-CAR FINDER. AUGUST W. GRANT, Detroit, Mich., assignor to Edward A. Hall and William C. Keller, Detroit, Mich. Filed May 12, 1904. Serial No. 59,994. (No model.)

Claim.—1. In a car-finder, the combination with the car-frame, of a fender-frame hinged at its rear end to the frame of the car and adapted at its forward end to swing downward by gravity into contact with the rails of the track in advance of the car-frame, pulleys journaled on the car-frame on either side thereof, a drum journaled centrally to the car-frame, chains attached directly to the opposite sides of the fender-frame passing upwardly over said pulleys and horizontally to and around said drum whereby the fender-frame becomes suspended above the track-rails to move freely in the arc of a vertical circle, means for rotating said drum to draw upon said chains and raise the fender, a ratchet-wheel upon the shaft of said drum having peripheral teeth, a plate upon the platform adjacent thereto, a curved detent pivoted at the center to said plate and adapted to engage the teeth upon the periphery of the ratchet, the engaging end of said detent being adapted to move vertically, a curved shoulder on said plate coinciding with and embracing the curved end of said detent when said detent is in engagement with the ratchet, a tread upon the free end of the detent to enable it to be raised at its curved end and disengaged from said ratchet-wheel to release the drum and allow the chains to run slack when the fender is down and avoid imparting to the fender the tilting movement of the car-frame.

2. In a street-car finder, the combination with the frame of the car, of the fender pivoted thereto so as to allow the forward end thereof to swing vertically, the upper side bars of the fender-frame lying close to the bottom of the car above the plane of the horizontal forward portion which is connected to the upper side bars by a vertical section and stands parallel with the track, chains attached directly to the opposite upper side bars of the fender-frame forward of said point of pivot and running freely to loosely suspend the forward end of the fender above the track and allow of a tilting and swaying movement thereof, said chains passing vertically over suitable rollers and horizontally to a rotary drum, means for rotating said drum to wind the chains thereon and raise the fender, means for locking the drum against rotation to maintain the fender in its raised position and means for unlocking said drum to permit the chains to unwind freely therefrom and the forward end of the fender to drop to the track by gravity.

699,770. ATTACHMENT FOR WINDOW-SEALER. MARION F. STEVENS and OTIS STEVENS, Indianapolis, Ind. Filed Mar. 10, 1902. Serial No. 57,699. (No model.)

Claim.—In a shade-rolling device, a base-plate having integrally-formed ears which carry threaded apertures, a seal-housing adapted to overlie the said ears, screws passing through the said housing and engaging with the apertures in the ears on the base-plate, a post integral with the housing and centrally mounted therein and which forms a bearing for the seal, a seal on the post which carries an integral recessed ratchet on one side, an integrally-formed sleeve on the other, the said sleeve forming a bearing for the spring, a spring secured to the sleeve and seal-housing, a pawl pivotally secured to the central post, the said pawl engaging at one end with the ratchet on the seal while the other end thereof is bent at right angle from the main body and formed into a hook, a leaf-spring secured to the seal-housing the free end of which rests on the pawl, whereby the said pawl is held into contact with the ratchet, a cord extending from the seal to the housing and engaging with the secondary seal secured to the shade-roller, whereby a means is provided for operating the window-shade, substantially as shown and described.

699,771. AUTOMATIC CUT-OFF GOVERNOR. GEORGE STERN, Fairport, N. H. Filed Apr. 24, 1901. Serial No. 67,289. (No model.)

Claim.—In a device for the purpose described, the combination consisting of an auxiliary eccentric ring supported and free to turn on the hub of a fly-wheel, means for holding same thereon, a main eccentric ring supported and free to turn on the periphery of the said auxiliary eccentric ring, means for preventing the main eccentric ring from working off the periphery of the auxiliary eccentric ring, the two weighted levers provided with adjustable weights on the free arm extensions thereof, means for pivotally attaching said weighted levers to the spokes or web of said fly-wheel shaft, the connecting-rods pivotally attached at one end to the two ends of the weighted levers and at the other end to the main eccentric ring, the connecting-rods pivotally attached to the weighted levers between the pivotal fulcrums and two ends thereof and to the auxiliary eccentric ring, the tension-springs fastened at one end to the free arm extensions of the weighted levers and the other end thereof being attached to a movable block on the adjustable tension-rods, the adjustable tension-rods, means for supporting same, all connected and operated substantially as described and illustrated for the purpose, substantially as set forth.

699,772. GUIDE FOR SEWING-MACHINE. RALPH STEWART, Chicago, Ill. Filed Jan. 24, 1903. Renewed Mar. 23, 1902. Serial No. 100,690. (No model.)

Claim.—1. A guide attachment for sewing-machines having in combination a plate, two independent gages adjustably secured to said plate, a guide proper having a stem adjustably mounted on said plate over said gages, flanges on said gages having notches and a dog on said stem adapted to engage in said notches, substantially as set forth.

2. A guide attachment for sewing-machines having in combination a guide proper, a two-part hinged arm and an eccentric by which the parts of said arm are hinged together, whereby the guide may be elevated by the turning of said eccentric, substantially as set forth.

3. A guide attachment for sewing-machines having in combination a guide proper, a two-part hinged arm by which said guide is supported, an eccentric journaled in one part of said arm, a screw projecting from said eccentric and being threaded in the other part of said arm and a nut on said screw, substantially as set forth.

4. A guide attachment for sewing-machines having in combination a guide proper, and a two-part hinged arm by which said guide is supported, the parts of said arm being reversely curved, substantially as set forth.

5. A guide attachment for sewing-machines having in combination a guide proper, a support to which said guide is rotatably secured, an arm for supporting said support and an eccentric by which said support is connected to said arm and by which eccentric said support may be bodily lifted to permit the support to pass over the goods without lifting the guide out of operative relation to the goods, substantially as set forth.

6. A guide attachment for sewing-machines having in combination a plate, two gages relatively adjustable, secured to said plate, a guide proper having a longitudinal stem crossing said plate adjacent to said gages and extending longitudinally of the adjustable movement of said gages, a dog carried by said stem and means whereby said dog is caused to attach said stem to either of said gages always at a definite or fixed point with reference to both the length of said stem and the length of the gage, substantially as set forth.

699,778. RATCHET SCREW-DRIVER. ISAAC B. STONE, Cleveland, Ohio, assignor of one-half to Ernest H. Stone, Cleveland, Ohio. Filed July 28, 1901. Serial No. 68,102. (No model.)

Claim.—1. In combination, a tool-stock, having a tool at each end, a removable handle adapted to cover one of the tools when the other is in use, and a yoked handle pivoted to the stock and adapted to rotate the same.

2. In combination, a tool-stock, a relatively stationary ratchet-thimble secured thereto, a relatively movable ratchet-block mounted upon the stock and adapted to engage the thimble, and a handle pivoted to the ratchet-block.

3. In combination, a tool-stock, a pair of non-rotatable ratchet-thimbles thereon having teeth inclined in opposite directions, a rotatable ratchet-block upon the stock between the thimbles having teeth at each end adapted to engage the teeth of the thimbles, and a reversible handle secured to the ratchet-block.

4. In combination, a reversible tool-stock having a tool at each end, a rotatable ratchet-block thereon, a yoked handle the arms of which are pivotally connected to the ratchet-block and adapted to rotate the same, and a ratchet-thimble upon the stock adapted to engage the block and rotate the stock.

5. In combination, a stock, a rotatable ratchet-block thereon having teeth at each end, a pair of longitudinally-yielding non-rotatable thimbles on the stock having oppositely-inclined teeth adapted to engage the teeth of the ratchet-block, means to retain either thimble out of engagement with the ratchet-block and a handle attached to the ratchet-block and adapted to rotate the same.

6. In combination, a stock having a tool at each end, a rotatable ratchet-block on the stock having teeth at each end, a yoked handle the

arms of which are pivotally attached to the ratchet-block so that it may be reversed relative to the tools or extended laterally as a lever, a pair of non-rotatable ratchet-thimbles on the stock having teeth adapted to engage the teeth of the ratchet-block in opposite directions, and means to retain either thimble out of engagement with the block.

7. In combination, a stock having a tool at each end, a rotatable ratchet-block on the stock having teeth at each end, a yoked handle pivotally attached to the ratchet-block so that it may be reversed relative to the tools or extended laterally as a lever, a removable handle adapted to cover the tool not in use and to fit between the arms of the yoked handle, a pair of non-rotatable ratchet-thimbles on the stock having teeth adapted to engage the teeth of the ratchet-block in opposite directions, and means to retain either thimble out of engagement with the block.

8. In combination, a ratchet-driven stock having a tool at each end, a yoked handle, the stock being pivotally mounted between the arms of the handle and reversible therein, and means to prevent pivotal turning of the stock, so as to retain the stock and handle right.

9. In combination, a stock, a tool at each end thereof, a ratchet-block rotatably mounted upon the stock having oppositely-inclined teeth at each end, non-rotatable ratchet-thimbles upon the stock having teeth adapted to engage the ratchet-block and turn the stock in opposite directions, springs bearing against the thimbles causing the same to normally engage the ratchet-block, means to retain either thimble out of engagement with the ratchet-block, rollers upon the stock, a yoked handle adapted to cover the tool not in use and to bear upon the rollers so as to prevent the rotation of the said tool therewith.

699,774. MACHINE FOR THE SIMULTANEOUS APPLICATION OF IMPREGATING OR OTHER POWER FOR OPERATING ROTARY MACHINERY. MARY H. SWIFT, Chicago, Ill., assignor of Edward D. Swift, deceased. Filed Nov. 4, 1900. Serial No. 26,593. (No model.)

Claim.—1. A machine, of the class of mechanism described, having two rotating wheels, and two idle or guide wheels, arranged in line, each with the other, and operating in the same plane, with caps or lugs formed on their external surfaces or perimeters; the two rotating wheels, adjusted closely to each other and mounted upon a cylindrical drum, and having rotary motion thereon; the drum, being hung upon and fixed to a shaft, for operative work; the two idle or guide wheels, being hung upon the shaft, upon which they have rotary motion; two endless chain belts, one chain belt being hung upon and running over one of the rotating wheels, and one idle or guide wheel, and the other chain belt being hung upon and running over the other rotating wheel and the other idle or guide wheel, the links of each chain belt being so formed as to engage the perimeters and caps or lugs of the wheels, upon and over which it is hung and run; two extension arms or rods, one end of one extension arm or rod being secured to the surface of one chain belt

at a point on a right line tangential to the perimeters of the wheels at their upper face, upon which it is hung, and one end of the other extension arm or rod being secured to the surface of the other chain belt at a point on a right line tangential to the perimeters of the wheels at their lower face, upon which it is hung, the opposite end of each extension arm or rod being secured to a cross-head, and having a reciprocating movement thereon; a cross-head, attached to the end of a reciprocating piston-rod, P; a lock, adjusted in the inner face of one side of each wheel mounted upon the drum, a friction-belt, H, encircling the periphery of the drum, and being a part of the lock, the lock being so constructed as to lock the wheel to the drum and unlock it therefrom, at each alternate reciprocating movement of the motive power, substantially as specified.

2. A machine, of the class of mechanism described, having two rotating wheels, A and A', and two idle or guide wheels, B and B', arranged in line, each with the other, and operating in the same plane, with caps or lugs formed on their external surfaces or perimeters; the two rotating wheels, A and A', adjusted closely to each other, and mounted upon a cylindrical drum, D, and having rotary motion thereon; the drum, D, being hung upon and fixed to a shaft, S, for operative work; the idle or guide wheels, B and B', being adjusted closely to each other upon an axle, S', and having rotary motion thereon; two endless chain belts, E and E', the chain belt, E, being hung upon and running over the wheels, A' and B', and the other chain belt, E', being hung upon and running over the wheels, A and B, the links of each chain belt being so formed as to engage the perimeters and caps or lugs of the wheels, upon and over which it is hung and run; two extension arms or rods, F and F', one end of one extension arm or rod, F, being secured to the surface of the chain belt, E, at a point on a right line tangential to the perimeters of the wheels, A' and B', at their upper face, upon which it is hung, and one end of the other extension arm or rod, F', being secured to the surface of the chain belt, E', at a point on a right line tangential to the perimeters of the wheels, A and B, at their lower face, upon which it is hung, and having reciprocating movement thereon; a cross-head, attached to the end of a reciprocating piston-rod, P; a lock, L, L', adjusted to the inner face of one side of each one of the wheels, A and A', the friction-belt, H, encircling the periphery of the drum, D, and being a part of the lock, the lock being so constructed as to lock the wheel to the drum and unlock it therefrom, at each alternate reciprocating movement of the motive power, substantially as specified.

3. In a mechanism of the class described, the combination of the two wheels, A and A', adjusted closely to each other upon the cylindrical drum, D; the drum, D, hung upon the shaft, S; the two wheels, B and B', adjusted closely to each other upon an axle, S'; the chain belt, E, hung upon and running over the wheels, A' and B; the extension arms or rods, F and F', one end of the arm or rod, F, being secured to the surface of the chain belt, E, and one end of the arm or rod, F', being secured to the surface of the chain belt, E', the opposite ends being secured to a cross-head, attached to the end of the motive piston-rod, P; the lock, L, L', adjusted to the inner face of one side of each one of the wheels, A and A', the friction-belt, H, encircling the periphery of the drum, D, and being a part of the lock, the lock being so constructed as to lock the wheel to the drum and unlock it therefrom, at each alternate reciprocating movement of the motive power, substantially as specified.

4. In a mechanism of the class described, the combination of the two wheels, A and A', mounted upon the cylindrical drum, D, the two wheels, B and B', adjusted upon the axle, the endless chain belt, E, hung upon the wheels, A and B, the endless chain belt, E', hung upon the wheels, A' and B', the extension arm or rod, F, secured to the chain belt, E, the lock, L, L', adjusted in the wheels, A and A', the segment, m, the bar, n, the lugs, n' and n'', the friction-belt, H, encircling the drum, D, the spring, A, and the bar, p, substantially as specified.

5. In a mechanism of the class described, the combination of the two wheels, A and A', the drum, D, the two wheels, B and B', the endless chain belts, E and E', the two extension arms or rods, F and F', the lock, L, L', the segment, m, the bar, n, the lugs, n' and n'', the friction-belt, H, encircling the drum, D, the spring, A, and the bar, p, substantially as specified.

6. In a machine of the class described, the combination of two rotating or driving wheels, each wheel having a circumferential exterior engaging or driving flange, a driven drum, on which the wheels are mounted to be substantially locked thereto, and unlocked therefrom, means for engaging and disengaging the wheels from the drum, operating for one wheel to be simultaneously disengaged as the other wheel is engaged; driving or driven chain belts, one for each wheel for intermittently and alternately advancing each wheel to impart a continuous rotation of the drum, and means for retaining the chain belts on a right line tangential to the exterior flange or perimeters of the rotating or driving wheels, substantially as specified.

7. In a machine of the class described, the combination of two rotating or driving wheels, each wheel having a circumferential exterior engaging or driving face, a driven drum, on which the wheels are mounted to be automatically locked thereto and unlatched therefrom, means for engaging and disengaging the wheels from the drum, operating for one wheel to be disengaged, as the other wheel is engaged; driving or draw chain belt, one for each wheel, for intermittently and alternately advancing each wheel to impart a continuous rotation of the drum, means for actuating the chain belt from a reciprocating motive power on a right line tangential to the exterior face or periphery of the rotating or draw wheel, and a shaft on which the drum is fixed, for the shaft to be continuously rotated from the drum, substantially as specified.

8. In a machine of the class described, the combination of two rotating or driving wheels, each wheel having a circumferential exterior, engaging or driving face, a drum on which the wheels are mounted to be automatically locked thereto and unlatched therefrom, means for engaging and disengaging the wheels from the drum, operating for one wheel to be disengaged, as the other wheel is engaged; driving or draw chain belt, one for each wheel, for intermittently and alternately advancing each wheel to impart a continuous rotation of the drum; two guide or carrying wheels, one for each rotating or draw wheel in line with and in the same plane as its rotating or driving wheel, and having a circumferential exterior, engaging or driving face, receiving the driving or draw chain belt, and means for actuating the chain belt from a reciprocating motive power, on a right line tangential to the exterior face or periphery of the rotating or driving wheel, substantially as specified.

9. In a machine of the class described, the combination of two rotating or driving wheels, each wheel having a circumferential exterior, engaging or driving face, a driven drum, on which the wheels are mounted, to be automatically locked thereto and unlatched therefrom, means for engaging and disengaging the wheels from the drum, operating for one wheel to be disengaged, as the other wheel is engaged; driving or draw chain belt, one for each wheel, for intermittently and alternately advancing each wheel to impart a continuous rotation of the drum; two guide or carrying wheels, one for each rotating or driving wheel in line with, and in the same plane as its rotating or driving wheel, and having a circumferential exterior, engaging or driving face, receiving the driving or draw chain belt, means for actuating the driving chain belt from a reciprocating motive power, on a right line tangential to the exterior face or periphery of the rotating or driving wheel; a shaft on which the drum is fixed for the shaft to be continuously rotated from the drum, and an axle for the guide or carrying wheel, substantially as specified.

10. In a machine of the class described, the combination of two rotating or driving wheels, each having on its exterior circumferential face or periphery a series of projecting caps or lugs, a driven drum, upon which the wheels are mounted to be automatically locked thereto and unlatched therefrom, a lock for each wheel to the drum, actuated by the advance of the wheel to engage the wheel and drum, and by the return of the wheel to disengage the wheel and drum; chain belt, one for each wheel for intermittently and alternately advancing each wheel to impart a continuous rotation to the drum, each chain in engagement with the exterior face or periphery of the drum, and the caps or lugs of its rotating or driving wheel; two guide or carrying wheels, one for each rotating or driving wheel, in line with, and in the same plane as its rotating or driving wheel, each guide or carrying wheel having on its circumferential exterior face or periphery, a series of caps or lugs corresponding to the caps or lugs on the rotating or driving wheel, and receiving the driving or draw chain belt, means for actuating the drive or draw chain belt on a right line tangential to the exterior face or periphery of the rotating or driving wheel, from a reciprocating motive power, on a right line tangential to the exterior face or periphery of the rotating or driving wheel; a shaft on which the drum is fixed to be continuously rotated from the drum, and an axle for the guide or carrying wheel, substantially as specified.

11. In a machine of the class described, the combination of two rotating or driving wheels, each having on its circumferential exterior face or periphery a series of projecting caps or lugs, a driven drum, upon which the wheels are mounted to be automatically locked thereto and unlatched therefrom, a lock for each wheel to the drum, actuated by the advance of the wheel to engage the wheel and drum, and by the return of the wheel to disengage the wheel and drum; chain belt, one for each wheel, for intermittently and alternately advancing each wheel to impart a continuous rotation to the drum, each chain in engagement with the exterior face or periphery of the drum, and the caps or lugs of its rotating or driving wheel; two guide or carrying wheels, one for each rotating or driving wheel, in line with, and in the same plane as its rotating or driving wheel, each guide or carrying wheel having on its circumferential exterior face or periphery a series of caps or lugs corresponding to the caps or lugs on the rotating or driving wheel, and receiving the driving or draw chain belt; an arm or rod attached, at its forward end, to the upper face of one of the chain belts, on a right line tangential to the exterior face or periphery of the rotating or

driving wheel of the chain belt, an arm or rod attached, at its forward end, to the under face of the other chain belt, on a right line tangential to the exterior face or periphery of the rotating or driving wheel of the chain belt; a cross-head having the rear ends of the arms or rods attached thereto; a piston-rod carrying the cross-head; a shaft, on which the drum is fixed to be continuously rotated from the drum, and an axle for the guide or carrying wheel, substantially as specified.

12. In a machine of the class described, the combination of the two rotating or driving wheels, each wheel composed of two sections or divisions, each division having an exterior body or rim, the body or rim of one division, having, also, a series of caps or lugs on its exterior face or periphery, and an interior diameter and width to receive the body or rim of the other division; a drum, on which the rotating or driving wheels are mounted, to be automatically locked thereto and unlatched therefrom; a lock for each wheel to the drum, actuated by the advance of the wheel to engage the wheel and drum, and on the return of the wheel, to disengage the wheel from the drum; a drive or draw chain belt for each wheel, each chain in engagement with the exterior face or periphery and caps or lugs of its wheel, and intermittently and alternately advancing the wheel for the two wheels to impart a continuous rotation of the drum, and means for actuating the drive or draw chain belt, each on a right line tangential to the exterior face or periphery of its rotating or driving wheel, from a reciprocating motive power, substantially as specified.

13. In a machine of the class described, the combination of the two rotating or driving wheels, each wheel composed of two sections or divisions, each division having an exterior body or rim, the body or rim of one division having, also, a series of caps or lugs on its exterior face or periphery, and an interior diameter and width to receive the body or rim of the other division; a drum, on which the rotating or driving wheels are mounted to be automatically locked thereto and unlatched therefrom; a lock for each wheel to the drum, actuated by the advance of the wheel to engage the wheel and drum, and on the return of the wheel to disengage the wheel from the drum; a drive or draw chain belt for each wheel, each chain in engagement with the exterior face or periphery and caps or lugs of its wheel, and intermittently and alternately advancing the wheel for the two wheels to impart a continuous rotation to the drum, a guide or carrying wheel in line with and in the same plane as its rotating or driving wheel, and having on its exterior face or periphery a series of caps or lugs corresponding with the caps or lugs of the rotating or driving wheel, and means for actuating the drive or draw chain belt, each on a right line tangential to the exterior face or periphery of the rotating or driving wheel from a reciprocating motive power, substantially as specified.

14. In a machine of the class described, the combination of two rotating or driving wheels, each wheel having a rim or ring body, a drum on which the rotating or driving wheels are mounted in juxtaposition, side by side, means for alternately locking the wheels to the drum and unlatching them therefrom automatically with the advance and return movement of the wheels; a drive or draw chain belt for each wheel, and means for actuating the chain belt from a reciprocating motive power, to intermittently and alternately advance the wheels and impart a continuous rotation to the drum, substantially as specified.

15. In a machine of the class described, the combination of the two rotating or driving wheels, each wheel having a rim or ring body, a drum, on which the rotating or driving wheels are mounted in juxtaposition, side by side, means for alternately locking the wheels to the drum and unlatching them therefrom automatically with the advance and return movement of the wheels; a drive or draw chain, and means for actuating the chain from a reciprocating motive power, to intermittently and alternately advance the wheels and impart a continuous rotation to the drum, and a shaft having the drum fixed thereto, for the shaft to be continuously rotated from the drum, substantially as specified.

699,775. PACKING LEVER. GEORGE T. THOMAS, Washington, D. C. assignor of one-half to GEORGE T. THOMAS, Washington, D. C. Filed Jan. 7, 1908. Serial No. 55,708. (No model.)

Claim.—1. The device provided with the receiving platform, and with portions extending beyond the platform capable of limited longitudinal play independently of the movement of the platform, substantially as set forth.

2. The device provided with the receiving platform, and with portions extending beyond the platform, the alternate portions capable of limited longitudinal play independently of the movement of the platform, substantially as set forth.

3. The combination of the reciprocating platform having portions and discharge openings between the portions, transverse blades in front and rear of said openings, and a channelled receiver into the channels of which the rear blades project, substantially as set forth.

4. The reciprocating platform with discharge openings and blades extending downward in front and at the rear of said openings, combined

with a receiver having channels into which the rear blades project, substantially as set forth.

5. The combination is a packing-section, of a reciprocating plunger and a trough for receiving the article to be packed adapted at the end to enter the packing box or receptacle and provided at said end with yielding sides, substantially as set forth.

6. The combination of the reciprocating plunger and a trough having yielding sides and a yielding cap, substantially as set forth.

7. The trough having a right bottom, side adapted to yield near the end of the trough for the passage of articles between them, a cap pivoted between the sides, and a plunger reciprocating in the trough, substantially as set forth.

8. The combination is a packing-section, of a trough having yielding side portions at each end and a double-ended plunger, and means for reciprocating it in the trough, substantially as set forth.

9. The combination with a reciprocating plunger, of a trough adapted at the end to enter the packing box or receptacle and its sides having the terminal portions pivoted to swing laterally, and springs for carrying the pivoted portions inward, substantially as set forth.

10. The combination with a reciprocating plunger, of a trough, side having the terminal portions pivoted to swing laterally, springs for carrying the pivoted portions inward, and a cap pivoted between the sides, substantially as set forth.

699,776. RUBBER IMPRESSION-TRAY. BENNY L. TOWNSHIP, Los Angeles, Cal. Filed July 28, 1904. Serial No. 78,108. (No model.)

Claim.—1. A lining for impression-trays composed of detached sections extending transversely to a line which coincides with the central tooth-line when the tray is used in taking an impression.

2. The device described having for impression-trays, comprising a plurality of sections which meet longitudinally on a line which coincides with the central tooth-line when the tray is used in taking an impression; said sections having opposed edges along their meeting-lines, substantially as described herein.

699,777. HEATING FIRE-WATER. FREDERICK H. TREVISEN, Cairo, Egypt. Filed Jan. 14, 1908. Serial No. 68,988. (No model.)

Claim.—1. A hot-water heater adapted for use with locomotives and other combined engines and boilers, arranged substantially above the boiler and comprising a cylindrical hot-water-containing vessel surrounded by an annular steam-chamber and traversed by tubes which open into a smoke-box at each end and serve to convey the waste gases from the furnace, said annular steam-chamber being also traversed centrally by a pipe which forms a continuation of the exhaust-steam pipe, substantially as herein described.

2. In a locomotive or other combined engine and boiler, the device described means for heating the hot-water heater, arranged horizontally above the boiler and whereof the tubes communicate at one end with the forward smoke-box and at the other end with the rear smoke-box, an exhaust-steam pipe led through the forward smoke-box and centrally through the tubular water-containing vessel, a smoke-stack attached to the rear smoke-box, and means for creating a blast at the rear extremity of the exhaust-steam pipe, substantially as herein described.

3. In a locomotive or other combined engine and boiler, the combination with a boiler B of a tubular water-heater A, a smoke-box C at the forward end of the said vessel, a smoke-box D at the rear end of the said vessel, an exhaust-steam pipe E traversing the first smoke-box and then, centrally, the hot-water-containing vessel, a blast-nozzle F at the rear extremity of the said pipe and a smoke-stack extending from the rear smoke-box substantially as herein described and for the purposes set forth.

4. In a locomotive or other combined engine and boiler, the combination with a boiler B of a tubular water-heater A, an annular steam-receiver I surrounding the said water-heater, a smoke-box C at one end of the heater and a smoke-box D at the other end thereof, an exhaust-steam pipe E extending through a central tubular passage in the water-heater, and a blast-nozzle F on the said exhaust-steam pipe, substantially as set forth for the purposes set forth.

5. In a locomotive or other combined engine and boiler, the combination with a boiler B of a tubular water-heater A, an annular steam-receiver I surrounding the said water-heater, a smoke-box C at one end of the heater and a smoke-box D at the other end thereof, an exhaust-steam pipe E extending through a central tubular passage in the water-heater, a blast-nozzle F on the said exhaust-steam pipe, a smoke-packet J situated above the fire-box and tubes in said packet communicating with the rear smoke-box D, substantially as set forth for the purposes set forth.

699,778. WATER-BAG. EDWARD H. UNGER, New York, N. Y. Filed Jan. 17, 1908. Serial No. 68,104. (No model.)

Claim.—1. An improved article of manufacture a multiple water-bag comprising a plurality of independent flexible water cells or compartments each complete in itself and united by flexible flattened connecting portions, said water-cells being in communication with each other by passages through said flattened connecting portions, as set forth.

2. An improved article of manufacture, a multiple water-bag comprising a plurality of independent flexible water cells or compartments each complete in itself and united by flexible flattened connecting portions, said multiple water-bag being provided with means for admitting water to, confining it in and discharging it from said water cells or compartments, as set forth.

3. An improved article of manufacture a multiple water-bag comprising a plurality of independent flexible water cells or compartments each complete in itself and united by flexible flattened connecting portions, said multiple water-bag having means for admitting water to one of said cells, and a communication between said cell and the others, as set forth.

699,779. COMBINED HEATING AND COOKING STOVE. JOHN L. VAN HORN, Florida, Tex. Filed June 22, 1901. Serial No. 61,611. (24 claims.)

Claim.—1. The herein-described combined heating and cooking stove comprising a body portion having a circular oven and a combustion-chamber; suitable partition-walls between the oven and the fire-box adapted to cause the products of combustion to extend entirely around said oven and thence under the sub-receiver to the chimney and a suitable opening in the upper portion of the combustion-chamber through which the fuel may be introduced, all substantially as specified and for the purpose set forth.

2. In a stove of the character described the combination with the body portion having combustion-chamber and circular oven, and a vertical channel between the same, of a deflector-plate at the top of said channel, the combustion-chamber having an opening for the introduction of the fuel and the chimney communicating with the body at the end opposite the oven outside the combustion-chamber, as set forth.

3. In a combined cooking and heating stove, a body portion having a combustion-chamber and a circular oven, a channel formed between the combustion-chamber and oven and closed at its top, a chimney communicating with the space around the combustion-chamber, and a diaphragm in the said channel having deflector at its upper end, whereby the products of combustion are forced to travel over the said channel around the oven up one side of said diaphragm and down the other and beneath the bottom of the combustion-chamber into the chimney, substantially as shown and described.

699,780. FOOT-REST. LEONARD W. WATSON, Brooklyn, N.Y. Filed Sept. 11, 1901. Serial No. 74,999. (No model.)

Claim.—1. A foot-rest, consisting of a turtle-shaped body, a base upon which the same is supported, a compressible back portion of said body, leg, head and tail members arranged between said base and said body, and means for actuating said leg, head and tail members to move inwardly and outwardly, substantially as set forth.

2. A foot-rest, consisting of a base, a compressible turtle-shaped body, supports arranged at the ends of said base to support said body, passages between said supports, leg, head and tail members adapted to move inwardly and outwardly in said passages, and means for producing the movement of said members, substantially as set forth.

3. A foot-rest, consisting of a base, a compressible turtle-shaped body, a supplemental base therein, spiral springs arranged between the back of said body and said supplemental base, an elliptical compression-spring passing through a slot in said supplemental base, leg, head and tail members, and means connecting said members and said elliptical compression-spring, substantially as set forth.

4. A foot-rest, consisting of a base, a turtle-shaped body having a flexible back, a supplemental base in said body, spiral springs arranged thereon, a transverse slot in said supplemental base, an elliptical compression-spring adapted to operate through the same, leg, head and tail members, and key-tongs connecting said members with said elliptical compression-spring, substantially as set forth.

699,781. BACK-PEDALING BRAKE. JAMES C. ASHTON and CHARLES KAPP, Buffalo, N.Y.; said Kapp assignor to said Ashton. Filed Dec. 9, 1901. Serial No. 66,168. (No model.)

Claim.—1. The combination of an axle, a wheel-hub mounted to rotate about said axle and provided with a brake-surface and a clutch-face, a brake-shoe located in said hub and movable longitudinally in the hub, means for holding said brake-shoe from rotation, a longitudinally-movable clutch device arranged between said brake-shoe and said clutch-face on the wheel-hub, said clutch device having a driving clutch-face cooperating with said clutch-face on the hub, a shifting device for moving said clutch device longitudinally to move the brake-shoe longitudinally, means for operating the shifting device, and a holding device to hold said clutch device from rotation while being moved longitudinally, substantially as set forth.

2. The combination of an axle, a wheel-hub mounted to rotate about said axle and provided with a brake-surface and a clutch-face, a brake-shoe longitudinally movable in said hub and having a brake-surface cooperating with said brake-surface on the hub, means for holding the brake-shoe from rotation, a longitudinally-movable clutch device arranged between said brake-shoe and said clutch-face on the hub, said clutch device having a driving clutch-face cooperating with said clutch-face on the hub, and having a part adapted to engage said brake-shoe to move the same longitudinally, means for shifting said clutch device longitudinally, and holding devices carried by said clutch device and acting to hold the same from rotation while being moved longitudinally, substantially as set forth.

3. The combination of an axle, a wheel-hub mounted to rotate about said axle and provided with a brake-surface and a clutch-face, a brake-shoe located in and longitudinally movable in the hub and provided with a braking-surface cooperating with said braking-surface on the hub, means for holding said brake-shoe from rotation, a rotatable driving-shaft, a longitudinally-movable clutch device provided with a clutch-face cooperating with said clutch-face on the hub, and with a face cooperating with a face on said brake-shoe, means operated by said driving-shaft for shifting said clutch device longitudinally, and a friction device carried by said clutch device and adapted to frictionally engage with said clutch-face on the hub in one position of the clutch device and with a face carried by the brake-shoe in another position of the clutch device, substantially as set forth.

4. The combination of an axle, a wheel-hub mounted to rotate thereon and provided with a brake-surface and a clutch-face, a brake-shoe arranged in said hub between said brake-surface and said clutch-face and having a face cooperating with said brake-surface and a friction-face, a longitudinally-movable clutch device arranged between said shoe and said clutch-face on the hub, means for moving the shoe longitudinally, a clutch-face on said clutch device cooperating with said clutch-face on the hub, friction holding devices carried by said clutch device, and means for holding said friction devices toward said friction-face on the brake-shoe and said clutch-face on the hub, substantially as set forth.

5. The combination of an axle, a hub mounted to rotate thereon and provided with a brake-surface and a clutch-face, a brake-shoe located in and longitudinally movable in said hub between said brake-surface and said clutch-face and having an internal friction-face, means for holding said brake-shoe from rotation, a clutch-ring arranged between said brake-shoe and said clutch-face on the hub and surrounded by said internal friction-face of the brake-shoe, a spring-pressed friction holding device seated in a recess in said clutch-ring and cooperating with said clutch-face on the hub and with said internal friction-face on the brake-shoe, and means for shifting said clutch-ring longitudinally, substantially as set forth.

6. The combination of an axle, a hub mounted to rotate thereon and provided with a brake-surface and a clutch-face, a brake-shoe arranged in the hub between said brake-surface and said clutch-face and provided with an internal friction-face, means for holding said brake-shoe from rotation, a longitudinally-movable clutch-ring having a clutch-face cooperating

with said clutch-face on the wheel-hub, and surrounded by said friction-face on said brake-disk, said clutch-ring having oppositely-arranged slots or depressions therein, a friction holding device located in each of said slots or depressions in the clutch-ring, a spring in each of said slots beneath said holding device and acting to move the same outwardly, said friction holding device having a face cooperating with said clutch-face on the hub and a face cooperating with said internal friction-face on said brake-disk, and means for moving said clutch-ring laterally and rotating the same, substantially as set forth.

7. The combination of an axle, a wheel-hub mounted to rotate thereon and having a brake-surface and a conical clutch-face, a brake-shoe arranged in said hub between said brake-surface and said conical clutch-face and having an internal friction-face, means for holding said brake-shoe from rotation, a clutch-ring arranged between said brake-shoe and said conical clutch-face on the hub, and provided with a conical clutch-face and extending within said internal friction-face of the brake-shoe, said clutch-ring having slots therein, a friction holding device arranged in each of said slots, a spring in each of said slots beneath said friction holding device and tending to move the same into engagement with said internal friction-face on the brake-shoe and said conical clutch-face on the hub, means for holding said friction holding devices and springs from longitudinal movement on the clutch-ring, means for moving said clutch-ring longitudinally into engagement with said brake-shoe or with said conical clutch-face on the hub, and means for rotating said clutch device, substantially as set forth.

8. The combination of an axle, a wheel-hub journaled to rotate about said axle and having a brake-surface and a conical clutch-face, a brake-shoe in said hub between said brake-surface and said clutch-face and having an internal friction-face, means for holding said brake-shoe from rotation, a clutch-ring arranged between said brake-shoe and said conical clutch-face on the hub, and provided with a conical clutch-face and extending within said internal friction-face of the brake-shoe, said clutch-ring having a peripheral slot therein, a spring-pressed friction holding device arranged longitudinally of the clutch-ring in said slot and having an inclined face circumferentially in line with the conical face of said clutch-ring, and a face coopering with said internal friction-face of the brake-shoe, means for preventing longitudinal movement of said friction holding device in said slot, and means for moving said clutch-ring laterally and for retaining the same, substantially as set forth.

899,782. MEANS FOR VENTILATING MILK AND CREAM DURING THE PROCESS OF SEPARATION. ARTHUR H. DANCHEWICZ, Hingham, Mass. Filed May 6, 1904. Serial No. 51,932. (No model.)

Claim.—1. An apparatus for ventilating milk and cream during their separation by means of a cream-separator, which apparatus comprises a cream-pipe connected to the cream-separator, a system of tubing connected to said cream-pipe and adapted to communicate with a source of fresh air, means for preventing foreign matter from passing with the air through said system, and means for preventing the admission of air from the work-room into the cream-pipe in combination substantially as described.

2. An apparatus for ventilating milk and cream during their separation by means of a cream-separator, which apparatus comprises a cream-pipe connected to the cream-separator, means for conveying a constant supply of pure air to said cream-pipe, and an automatic counterweighted valve adapted to close the discharge end of said cream-pipe in combination substantially as and for the purposes set forth.

3. An apparatus for ventilating milk and cream during their separation by means of a cream-separator, which apparatus comprises a cream-pipe connected to the cream-separator, a system of tubing connected to said cream-pipe and adapted to communicate with a source of fresh air, means for preventing foreign matter from passing with the air through said system, and an automatic counterweighted valve adapted to close the discharge end of said cream-pipe, in combination, substantially as and for the purposes set forth.

699,788. VAULT-LIGHT. LOUIS BRAM, New York, N. Y., assignor of one-half to Joseph Bucklebach, New York, N. Y. Filed Nov. 1, 1901. Serial No. 66,762. (No model.)

Claim.—1. The combination of wrought Z-iron all-base having grooves cut or otherwise formed therein, wrought angle-iron base B, the iron base B to fit into the grooves of the Z-iron all-base, wrought flat-iron transverse base C, and glass half-spheres, substantially as described, and for the purpose specified.

2. The combination of wrought Z-iron sill-bars having grooves cut or otherwise formed therein, wrought flat-iron transverse bars C, wrought angle-iron bars B, the iron bars B to fit into the grooves of the Z-iron sill-bars, and reflecting bull's-eye substantially as described and for the purpose specified.

899,784. ELECTROGRAPHICALLY-PRINTING TYPE-WRITER. STROUD
A. BROWN, New York, N. Y. Filed June 19, 1900. Serial No. 89,784.
(No model.)

Claim.—1. A type-writing machine having a longitudinally-traveling paper-carriage, means for supporting the paper therefrom, a platen, types, the platen-surfaces and types being of electrically-conductive materials normally insulated from each other and adapted to receive the paper between them, means for selecting the desired type and for bringing the selected type and the platen into contact with opposite sides of the paper at a common printing-point whereby the circuit is closed through the paper, and connections from platen and types to opposite poles of an electric battery.

2. In a type-writing machine the combination of a platen, means for securing the paper thereto, types, keys and means controlled by said keys for selecting and successively impressing the types upon the paper, the platen and types having electrically-conductive surfaces insulated from each other and adapted to be connected with opposite poles of an electric battery.

2. A type-writing machine having a platen for the reception of the paper, types, the platen-surface and types being of electrically-conductive materials and adapted to be respectively connected with opposite poles of an electric battery, keys for selecting and presenting the types at a common printing-point, and means for causing relative movement of paper and printing-point to print a succession of lines upon the paper.

4. A type-writing machine having a longitudinally-traveling platen provided with a metallo foil covering insulated from the types, means for securing the paper upon the platen, types, means for collecting and presenting the types to the platen to print a series of lines, and means for connecting said foil covering and types respectively with opposite sides of an electric battery.

5. A type-writer having a platen-carriage and a platen provided with an electrically-conductive surface, types and means for selecting and successively presenting the types at a common printing-point, means for causing the types to be impressed upon the paper to print a series of lines, an inclined bar and a brush engaging with the platen, one carried by the carriage and the other stationary, a brush connected with said bar and engaging said conductive surface on the platen and a battery connected from opposite ends respectively with the bar-engaging brush and with the types.

3. In a type-writing machine the combination of a platen having an electrically-conductive surface, means for covering thereto a sheet of electrically-prepared paper, a series of types, said platen and types being electrically insulated from each other and adapted to be connected with opposite poles of an electric battery, and means for bringing said type con-

continuously in contact with the paper upon said plates at a common printing-point, whereby a current of electricity is caused to flow through said sheet of paper at the point of contact of said types with the plates.

7. In a type-writing machine the combination of a longitudinally-traveling paper-carriage, a platen having an electrically-conductive surface insulated from the types, a plurality of types and means for presenting them at a common printing-point, said platen-surface and types being connected with opposite poles of an electric battery.

8. In a type-writing machine the combination of a plurality of type-carriages and means for bringing them successively in contact with the paper, at a common printing-point, a platen having an electrically-conductive surface insulated from the types, the types and platen-surface being connected with opposite poles of an electric battery, and means for causing relative movement of platen and printing-point to form a series of printed lines.

9. In a type-writing machine the combination of a longitudinally-traveling paper-carriage, means for securing the paper thereon, types, an impression member cooperating with the types, means controlled by the keys for selecting and presenting the types at a common printing-point and means for impressing the paper between the types and the impression member at said common printing-point, said impression member and the types having electrically-conductive surfaces mutually insulated and adapted to be connected with opposite poles of an electric battery.

10. In a type-writing machine the combination of a longitudinally-traveling paper-carriage, means for securing the paper thereon, types, an impression member adapted to cooperate with the selected type to form a printing-couple, keys, and means controlled by the keys for selecting the types and successively presenting them at a common printing-point and means for advancing one member of the printing-couple to impress the type upon the paper, said impression member and the types having mutually-insulated and electrically-conductive surfaces which are adapted to be connected with opposite poles of an electric battery.

699,785. HINGED LIFT. JEROME T. BROWN, Springfield, Mass., assignor to Oliver A. Miller, Brockton, Mass. Filed Apr. 2, 1906. Serial No. 13,171. (No model.)

Claim.—1. A hinged lift having a fore part, a heel part, and a hinge connecting said parts, said hinge comprising two members of which one is provided with a finger or projection and the other is formed with a stationary abutment and a movable lock adapted to receive said finger or projection between them.

2. A hinged lift having a hinge comprising two members secured in the respective parts of the lift, and a pin connecting said hinge members, the member for the heel part carrying a sliding lock movable longitudinally of the lift, and the member for the fore part having a projection extending rearwardly and adapted to be engaged by the lock.

3. A hinged lift having a hinge comprising two members and a pin, the member for the heel part having two forwardly-projecting webs, and the member for the fore part having a web lying between the first-mentioned webs and pivoted therein by the pin, the first-mentioned member having a lock movable longitudinally of the lift into engagement with the web of the second-mentioned member.

4. A hinged lift having a hinge comprising two members connected by a pin, the member for the fore part having a rearwardly-projecting web, and the member for the heel part having parallel webs to receive the web of the first-mentioned member, said member for the heel part also having a stop to limit the movement of the other member when it has reached the extremity of its movement, and a lock to hold said other member against said stop.

699,786. BATH ATTACHMENT. OLIVER GARFINKEL, Yonkers, N. Y. Filed Sept. 10, 1901. Serial No. 74,598. (No model.)

Claim.—1. As an article of manufacture, a flexible sheet having secured thereto a strip of flexible material having central projecting head, and outwardly-extending flanges secured to the sheet, and perforations in said head, as and for the purposes set forth.

2. As an article of manufacture, a flexible sheet having lateral ducts formed on its upper surface by headed strips having edges connected to the sheet, perforations in the head of said strip, and other strips likewise formed, extending between the lateral ducts, and a passage from the channel of one strip to that of the other, as and for the purposes specified.

3. The combination in an article of the class described, of a flexible and waterproof or water-repellent sheet, the parallel ducts, and the parallel longitudinal ducts connecting the lateral ducts, substantially as described.

4. The combination in an article of the class described, of the flexible waterproof or water-repellent sheet, the lateral and parallel and perforated ducts, and the longitudinal ducts connecting two of the lateral ducts, the adjacent ends of the longitudinal ducts being staggered relative to each other, substantially as described.

5. The combination in an article of the class described, of the sheet 1, the strip 5 secured thereto having the head 6 and projecting flanges 7, an aperture 20 in the head, another strip 15 having the flanges 16 and end flange 18, the flanges 18, 19, being secured upon the flange 7, as and for the purposes described.

6. In an article of the class described, the combination with the sectional ring, the sections being hinged together, a shield having component spray-dots, the hinge being below the sections, depending ends or chains secured at their lower ends, one adjacent each of the section ends, and others at a point removed from the hinge, and a suspending ring uniting the outer ends of the chains together.

7. In a bath-shield-suspending ring, the combination with the segmental sections hinged at their ends together by longitudinally-disposed pivots, shields depending from each section, each shield having a chain or cord extending from the ring-section, and a ring at the other end of the chain or cord, uniting them together, substantially as described.

699,787. ELECTRIC-RAILWAY SYSTEM. THOMAS L. GARDNER, Synt, N. Y., assignor to International Electric Traction Company, a Corporation of West Virginia. Filed Aug. 28, 1904. Serial No. 71,682. (No model.)

Claim.—1. In an electric-railway system track-rails, intersecting track-rails to form a crossing, a closed conduit extending adjacent said track-rails, a continuous and a sectional conductor in said conduit, a sectional contact-rail adjacent said conduit connected to said sectional conductor, the sections of said contact-rail being above the level of said intersecting track-rails at said crossing and insulated therefrom, a trolley in said conduit to connect said conductors, a car-magnet mounted on a car to control said trolley, an elongated contact-disk mounted on said car to make contact with said contact-rail, the intersecting track-sections above said conduit being formed of manganese steel to provide a non-magnetic housing for said conduit.

2. In an electric-railway system embodying track-rails, and a closed conduit, intersecting track-rails forming a crossing, a sectional contact-rail electrically connected from said conduit by magnetic means, said contact-rail being higher than said intersecting track-rails at said crossing, the intersecting track-rails over said conduit being non-magnetic so as to be free from interference with said conduit.

3. In an electric-railway system embodying a sectional contact-rail, a closed conduit and magnetically-actuated means in said conduit to charge said contact-rail, and a non-magnetic track-section.

4. In an electric-railway system embodying a sectional contact-rail, a closed conduit and magnetically-actuated means in said conduit to charge said contact-rail, a permanent-steel track-section forming a non-magnetic housing for said conduit.

5. In an electric-railway system, track-rails, a magnetically-operated closed conduit and sectional contact-rails intersecting at a crossing, there being a section of said sectional contact-rails within the track-rails at said crossing, said contact-rails being elevated above said track-rails.

6. In an electric-railway system, track-rails, a magnetically-operated closed conduit and a sectional contact-rail parallel to said track-rails, intersecting track-rails to form a crossing, there being an insulated section of said sectional contact-rail between said intersecting track-rails, insulating-blocks to insulate said sectional contact-rail from said intersecting track-rails, said sectional contact-rails and said insulating-blocks being elevated above said track-rails.

7. In an electric-railway system, track-rails, an intersecting sectional contact-rail elevated above said track-rails at its intersection with the same and elevated insulating-blocks between said contact-rail and said track-rails.

8. In an electric-railway system track-rails, magnetically-operated closed conductors and sectional contact-rails intersecting at a crossing, said contact-rails being elevated above said track-rails at said crossing and being formed with depressed non-magnetic portions where they pass over said conductors.

9. In an electric-railway system track-rails, closed conductors and sectional contact-rails intersecting at a crossing, said contact-rails being elevated above said track-rails at said crossing and being formed with non-magnetic sections above said conductors, a contact-disk, a car-magnet and means to maintain said car-magnet out of contact with said contact-rails.

10. In an electric-railway system, track-rails, a magnetically-operated closed conduit parallel to said track-rails, intersecting track-rails to form a crossing said intersecting track-rails being formed with non-magnetic sections over said conduit.

11. In an electric-railway system, track-rails, magnetically-operated closed conductors parallel to said track-rails and sectional contact-rails of magnetic material parallel to and removed from said conductors intersecting at a crossing, there being non-magnetic sections of said sectional contact-rails over the intersecting conductors.

699,788. HINGING-CASE FOR PAMPHLETS. DR. FRANK L. CLARK, Philadelphia, Pa. Filed Oct. 28, 1905. Serial No. 24,884. (No model.)

Claim.—1. In a hinging-case, the combination of a cover and a plurality of flexible elements extending transversely to the back thereof, with a plurality of leaf receiving and retaining clips and means on said clips engaging said flexible elements.

2. In a hinging-case, the combination of a cover, and a plurality of flexible elements secured to the cover and extending transversely across the back thereof, with a plurality of clips, means securing leaves or sheets in said clips and devices operating the clips to the flexible elements.

3. In a hinging-case, the combination of a cover or casing, transverse supporting-strips, of flexible material, connected to the back of said cover, connecting-clips adapted to receive a plurality of leaves or sheets, means for securing leaves or sheets in said clips, and means for attaching said clips to the supporting-strips.

4. In a hinging-case, the combination of a cover or casing, transverse supporting-strips, of flexible material, connected to the back of said cover, a plurality of connecting-clips, each channelled to receive an alignment of leaves or sheets and having a tongue for attachment to a supporting-strip, and sheet-fasteners for securing leaves or sheets in the connecting-clips.

5. In a hinging-case, the combination of a cover or casing, transverse supporting-strips, of flexible material, connected to the back of said cover, blocks or clip-cases fixed to the sides of the supporting-strips which adjust the back, connecting-clips each channelled to receive an alignment of leaves or sheets and having a tongue adapted to embrace a clip-end, and sheet-fasteners for securing leaves or sheets in the connecting-clips.

6. In a hinging-case, the combination of a cover or casing, transverse supporting-strips, of flexible material, connected to the back of said cover, a plurality of connecting-clips each channelled to receive an alignment of leaves or sheets, means for securing leaves or sheets in the connecting-clips, means for attaching clips, when connected to an alignment of leaves or sheets, to the supporting-strips, and means for covering spaces between alignments and connecting the connecting-clips.

7. In a hinging-case, the combination of a cover or casing, a transverse supporting-strip, of flexible material, connected to the back of said cover, a connecting-clip of light metal bent into channel form in transverse section and having openings in its sides to receive a sheet-fastener and a tongue by which it is attached to the supporting-strip, and a sheet-fastener adapted to pass through the openings of the clip and secure an alignment of sheets or leaves therein.

8. The combination of a hinging-case, and a channelled clip having a tongue secured to one end of the clip and extending therefrom and provided with a catch-shoulder for engagement with the other end of the clip.

9. A channelled hinging-clip having a tongue secured to one end of the clip and extending therefrom and provided with a catch-shoulder for engagement with the other end of the clip.

699,789. TEMPORARY BLINDER. FRANK L. CLARK, Philadelphia, Pa. Filed Oct. 28, 1905. Serial No. 24,885. (No model.)

Claim.—1. In a temporary blinder, the combination of a channel-shaped back having lateral openings, sides flexibly connected to the back, an end gage fixed to the back, a perforator adapted to pass through a lateral opening of the back, and a spring-arm connecting the perforator to the back.

2. In a temporary blinder, the combination of a channel-shaped back having lateral openings adjacent to its ends, sides flexibly connected to the back, an end gage fixed to the back, two perforators each adapted to pass through one of the lateral openings of the back, and connections coupling said perforators to an intermediate stud or pivot fixed to the back.

3. In a temporary blinder, the combination of a channel-shaped back having lateral openings, sides flexibly connected to the back, an end gage fixed to the back, sliding-plates secured to the inside of the back and having lateral openings registering with the openings thereof, sliding-plates being on the outside of the back and having openings registering with the openings thereof and of the sliding-plates and end tongues engaging the openings thereof.

the stiffening-plates, and a perforator connected to the back and adapted to pass through an opening thereof and of the adjacent stiffening and facing plates.

699,790. SAFETY ATTACHMENT FOR TRUNKS OR BOXES. JOHN T. COLLIER, Hartford, Conn. Filed Aug. 27, 1901. Serial No. 73,672. (No model.)

Claim.—1. An attachment consisting of a plate bearing a lever, a binding-plate with openings, a loop-plate having a loop adapted to receive the lever, and a flexible strap rove through the openings in the binding-plate and having one end attached to the lever-plate and the other end attached to the loop-plate, substantially as specified.

2. An attachment consisting of a plate provided with outwardly-projecting ears which bear a lever, a binding-plate with openings, a loop-plate having a loop adapted to receive the lever and the ears so that the strain of the loop-plate will be resisted by the ears, and a flexible strap rove through the openings of the binding-plate and having one end attached to the lever-plate and the other end attached to the loop-plate, substantially as specified.

3. An attachment consisting of a plate bearing a lever, a binding-plate with openings and projecting lugs, a loop-plate having a loop adapted to receive the lever, and a flexible strap rove through the openings of the binding-plate and having one end attached to the lever-plate and the other end attached to the loop-plate, substantially as specified.

4. An attachment consisting of a plate having outwardly-projecting ears with undercut edges, and bearing a lever with a curved detaching-lug, a binding-plate with openings, a loop-plate with an opening adapted to receive the lever and the ears, and a flexible strap rove through the binding-plate and having one end attached to the lever-plate and the other end attached to the loop-plate, substantially as specified.

5. An attachment consisting of a plate having outwardly-projecting ears bearing a lever, a binding-plate having openings, a loop-plate having openings, one of which is adapted to receive the lever and the ears, and a flexible strap rove through the openings in the binding-plate and having one end attached to the lever-plate and the other end rove through openings of the loop-plate, substantially as specified.

6. An attachment consisting of a plate having outwardly-projecting ears with undercut edges, and bearing a lever, a loop-plate with an opening adapted to receive the lever and the ears so that the strain of the loop-plate will be resisted by the ears, and a flexible strap rove through the loop-plate and attached to the lever-plate, substantially as specified.

699,791. LOCOMOTIVE-BELLER. SAMUEL G. CHASELEY, Philadelphia, Pa., assignor of one-half to Frank A. Winder, Philadelphia, Pa. Filed Oct. 21, 1901. Serial No. 73,682. (No model.)

Claim.—1. In a locomotive-beller, water fire-box, a plurality of longitudinally-extending water-tubes joining the front and rear portions of said water fire-box, a plurality of transversely-arranged water-tubes arranged in series and having different inclinations joining the sides of the fire-box, and located above said longitudinally-extending tubes, a fine leading from the combustion-chamber to the smoke-box, and water-tubes located in said fine.

2. A locomotive-beller consisting of a water fire-box, a plurality of longitudinally-extending water-tubes joining the front and rear legs of said water fire-box, the rear extremities of said tubes being deflected downwardly, a plurality of transverse water-tubes located in the combustion-chamber above said longitudinally-extending tubes, said transverse tubes being arranged in series and having different inclinations, a fine leading from the combustion-chamber to the smoke-box of the boiler, and water-distributing tubes located in said fine, the lower portion of said fine being arc-shaped and serving as a tube-sheet for the reception of the lower ends of said water-tubes.

chamber above said longitudinally-extending tubes, said transverse tubes being arranged in series and having different inclinations each curve inclined in opposite directions, a fine leading from the combustion-chamber to the smoke-box of the boiler, and water-distributing tubes located in said fine.

3. A locomotive-beller consisting of water fire-box surrounding the combustion-chamber, a plurality of longitudinally-extending water-tubes joining the front and rear legs of said water fire-box, the rear extremities of said tubes being deflected downwardly, a plurality of transverse water-tubes located in the combustion-chamber above said longitudinally-extending tubes, said transverse tubes being arranged in series and having different inclinations, a fine leading from the combustion-chamber to the smoke-box of the boiler, and water-distributing tubes located in said fine, the lower portion of said fine being arc-shaped and serving as a tube-sheet for the reception of the lower ends of said water-tubes.

4. In a locomotive-beller, the combination of a water fire-box, a plurality of longitudinally-extending tubes extending between the front and rear portions of said fire-box, a series of transversely-arranged tubes located in the combustion-chamber above said longitudinally-extending tubes, said transverse tubes being longitudinally inclined and arranged in staggered order, a fine leading from said combustion-chamber to the smoke-box, the lower portion of said fine being arc-shaped and the upper portion of said fine being also curved, and water-tubes joining the upper and lower portions of said fine, the central water-tubes being substantially vertical and the outer water-tubes having a greater inclination outwardly than said central water-tubes.

5. In a boiler, a water fire box, a plurality of longitudinally-extending tubes, located between the front and rear portions of said fire-box, a series of transversely-arranged tubes, located in the combustion-chamber above said longitudinally-extending tubes, said transverse tubes being in series and each curve inclined in opposite directions, a fine leading from said combustion-chamber to the smoke-box, and water-tubes joining the upper and lower portions of said fine, the central water-tubes being substantially vertical and the outer water-tubes having a greater inclination outwardly than said central water-tubes.

699,792. CARTER. ROSE DAVID, New York, N. Y., assignor to Standard Carter and Wheel Company, a Corporation of West Virginia. Filed Aug. 17, 1901. Serial No. 73,683. (No model.)

Claim.—1. In a meter, the combination of a vertical shaft or stem, provided with a suitable collar formed in one piece therewith, and forming a truck-plate; a horn carrying a roller at one extremity and forming at its other extremity an elongated bearing for holding the extremity of the shaft in a vertical position, capable of supporting a ball-cap; a ball-cap independent of and supported by the horn; and a series of steel balls

in the cap forming a bearing with the collar upon the shaft, upon which the meter rotates.

2. In a meter, the combination of a vertical shaft or stem provided with a suitable collar formed in one piece therewith and forming a truck-plate; a horn carrying a roller at one extremity and forming at its other extremity a bearing for holding the extremity of the shaft in a vertical position; a bearing arranged to fit into the bearing, engaged at the top to form a cap, and a series of steel balls in the cap forming a bearing with the collar upon the shaft upon which the meter rotates.

3. In a meter, the combination of a vertical shaft or stem provided with a suitable collar formed in one piece therewith and forming a truck-plate; a horn pressed or struck up from a single piece of steel so as to form in the center an elongated bearing for holding the shaft in a vertical position, provided with shoulders forming a bearing for a ball-cap and bent so as to form parallel horns arranged to hold a roller; a roller carried in the horns and a cap supported in the bearing and a series of steel balls in the cap forming a bearing with the collar upon the shaft upon which the meter rotates.

699,793. CONDENSING APPARATUS. ROBERT S. BROWN, Cleveland, Ohio. Filed Jan. 12, 1902. Serial No. 69,102. (No model.)

Claim.—1. Condensing apparatus comprising a water-receiving chamber; means for draining the said chamber of liquid received thereby or formed therein; means for conducting gases and vapors into the said chamber; a water-distributing pipe-connection arranged within and transversely of the said chamber, which pipe-connection is closed at its lower end and has slots formed in the sides and extending longitudinally thereof, and a water-supply pipe arranged to feed water to the said water-distributing pipe-connection.

2. Condensing apparatus comprising a casing forming a primary chamber and having a head at its upper end over the said chamber; means for draining the said chamber of liquid received thereby or formed therein; means for conducting gases and vapors into the said chamber; means for distributing water in the said chamber; a dome upon the above-said head; means for supplying water to the chamber of the dome and an upright tube extending through the chamber of the dome and in open relation, at its lower end, with the primary chamber of the condenser, and having lateral apertures arranged to discharge water from the chamber of the dome into the passage-way formed by the said tube.

means for distributing water in the said chamber; a dome upon the above-said head; means for supplying water to the chamber of the dome, and a tube extending through the chamber of the dome and in open relation with the primary chamber of the condenser, which tube has lateral apertures arranged to discharge water from the chamber of the dome into the passage-way formed by the said tube.

3. Condensing apparatus comprising a casing forming a primary chamber and having a head at its upper end over the said chamber; means for draining the said chamber of liquid received thereby or formed therein; means for conducting gases and vapors into the said chamber; means for distributing water in the said chamber; a dome upon the above-said head; means for supplying water to the chamber of the dome and an upright tube extending through the chamber of the dome and in open relation, at its lower end, with the primary chamber of the condenser, and having lateral apertures arranged to discharge water from the chamber of the dome into the passage-way formed by the said tube.

4. Condensing apparatus comprising a casing forming a primary chamber and having a head at its upper end over the said chamber; means for draining the said chamber of liquid received thereby or formed therein; means for conducting gases and vapors into the said chamber; means for distributing water in the said chamber; a passage-way extending upwardly from and in open relation, at its lower end, with the said chamber; means for conducting water into the said passage-way, and a head arranged in the upper end of the above-said chamber and above the above-said water-distributing means and having an aperture below the lower end of the above-said passage-way, substantially as and for the purposes set forth.

5. Condensing apparatus comprising a casing forming a primary chamber and having a head at its upper end over the said chamber; means for draining the said chamber of liquid received thereby or formed therein; means for conducting gases and vapors into the said chamber; means for distributing water in the said chamber; a dome upon the above-said head; means for supplying water to the chamber of the dome; an upright tube extending through the chamber of the dome and in open relation, at its lower end, with the primary chamber of the condenser, and having lateral apertures arranged to discharge water from the chamber of the dome into the passage-way formed by the said tube, and a head suspended in the upper end of the primary chamber above the above-said water-distributing means and having an aperture below the lower end of the above-said tube, substantially as and for the purposes set forth.

6. Condensing apparatus comprising a casing forming a primary chamber and having an upwardly-bulging concave-concave head at its upper end over the said chamber; means for draining the said chamber of liquid received thereby or formed therein; means for conducting gases and vapors into the said chamber; means for distributing water in the said chamber; a dome upon the above-said head; means for supplying water to the chamber of the dome; an upright tube extending through the chamber of the dome and in open relation, at its lower end, with the primary chamber of the condenser, and having lateral apertures arranged to discharge water from the chamber of the dome into the passage-way formed by the said tube, and an upwardly-bulging concave-concave head arranged within the upper end of the primary chamber above the above-said water-distributing means and perforated below the lower end of the above-said tube, substantially as and for the purposes set forth.

7. Condensing apparatus comprising a casing forming a primary chamber and having a head at its upper end over the said chamber; means for draining the said chamber of liquid received thereby or formed therein; means for conducting gases and vapors into the said chamber; means for distributing water in the said chamber; a dome upon the above-said head; means for supplying water to the chamber of the dome, and a chamber tube extending upwardly through the chamber of the dome and in open relation at its lower end with the primary chamber of the condenser, and having lateral apertures arranged to discharge water from the chamber of the dome into the passage-way formed by the said tube.

699,794. VERGULE FOR AWL OR KNIFE HANDLES. RITA HOWARD, Webster City, Iowa. Filed Dec. 26, 1901. Serial No. 69,103. (No model.)

Claim.—A tapering metal ferrule closed at its small end and provided with an aperture in the center of the closed end and two parallel

longitudinal ribs on its outside to produce a groove and a guard projecting at right angles from the inner ends of the ribs and groove, for the purpose stated.

699,795. APPARATUS FOR ROLLING ENGINES UPON STRIPS
OR BARS. JAMES BYRNE and WILLIAM D. BYRNE, Philadelphia, Pa.
Filed Dec. 31, 1898. Serial No. 617,574. (No model.)

Claim.—1. In an apparatus of the character named, a roll for making ornamental configurations, consisting of an ornamental ring or collar having therein the device to be impressed, the portions adjacent to said device being peripherally turned or finished and a plurality of roll-sections having turned or tread shoulders thereon, adapted to contact with said ring or collar, in combination with means for clamping said collar and sections together.

2. In an apparatus of the character named, a roll for making ornamental configurations, consisting of an ornamental ring or collar having therein the device to be impressed, the portions adjacent to said device being peripherally turned or finished, a plurality of roll-sections having turned or tread shoulders thereon, adapted to contact with said ring or collar, and means for clamping said collar and sections together, in combination with a second roll located in proximity to said first-mentioned roll and means for rotating one of said rolls.

3. In an apparatus of the character named, a roll for making ornamental configurations, the same consisting of an ornamental ring or collar having cut therein the device to be impressed, the portions adjacent to said device being peripherally turned or tread so as to impart a finished appearance to the edges of the article rolled, and a plurality of roll-sections having turned or tread shoulders thereon, adapted to contact with said ring or collar, in combination with means for clamping said collar and sections together.

4. In an apparatus of the character named, a collar or ring having cut in the periphery thereof a design or device, in combination with a roll having a turned or tread shoulder thereon, adapted to contact with said collar, a loose collar having a turned or tread shoulder adapted to contact with said first-mentioned collar and means for clamping said collars in position.

699,796. TYPE-WRITING MACHINE. JAMES FRANK, New York, N. Y., and CARL GARDNER, Greenville, S. C., joint inventors; assignors to said Frank. Filed May 14, 1901. Serial No. 66,187. (No model.)

Claim.—1. In a type-writing machine, the combination of a carriage-plate having grooves in its upper and lower edges, a grooved rail beneath said plate, a grooved rail above said plate, balls placed in the upper and lower grooves, a spacer 20 perforated to receive the balls in the lower grooves, arms 41 connected to said spacer, a spacer connected to the upper ends of the arms 41 and perforated to receive the balls in the upper grooves, said arms and said spacers being integral and the arms 41 extending up in rear of said carriage-plate, and the upper spacer including a forwardly-extending and upturned rack 43 comprising a portion in front of the upper rail, a pinion 45 mounted upon the carriage-plate below said rack and meshing therewith, a pinion 47 having twice the diameter of pinion 45 and rigidly secured thereto, and a rack 46 mounted upon the upper rail above said pinion 47 and meshing with pinion 47.

2. In a type-writing machine, the combination of a carriage-plate, a letter-spacing rack mounted upon forwardly-extending arms so as to form a ball, rack-shaft 56 carried at opposite ends of the plate and fixed at

their inner ends to the forward ends of said arms, and forwardly-extending finger-levers fixed to the outer ends of said rack-shafts.

3. In a type-writing machine, the combination of a carriage-plate, rack 20 arranged in rear thereof, forwardly-extending arms 58 fixed upon said rack, rack-shaft 56 journaled in opposite bases 54 and at their inner ends secured to the forward ends of said arms 58, forwardly-extending levers 59 fixed to the outer ends of said rack-shafts and provided with finger-pieces 60, and a spring 61 compressed between an arm 58 and a portion of said shaft.

4. In a type-writing machine, the combination of a carriage-plate, a letter-spacing rack arranged in rear thereof, forwardly-extending arms having flanged ends to which said rack is rabbeted and secured by screws, means for hinging the forward ends of said arms upon said plate, and a forwardly-extending finger-lever for engaging said rack.

5. In a type-writing machine, the combination of a carriage-plate, a letter-spacing rack arranged in rear thereof, arms 58 having flanged rear ends 59 to which said rack is rabbeted and secured by screws 51, rack-shaft 56 mounted in opposite bases 54 carried upon the forward side of said plate and at their inner ends pinned to the forward ends of said arms 58, and forwardly-extending finger-levers 59 secured by screws 56 upon the outer ends of said rack-shafts.

6. In a type-writing machine, the combination with a carriage and suitable letter-spacing device therefor, of a bar extending longitudinally of the carriage and pivotally supported upon the framework, key-locking device, including a part mounted upon said carriage and cooperating with a projection carried upon the said pivoted bar, arm 80 projecting from said bar, link 82 loosely connecting lever 83 to said arm 80, key-lever 84 extending to the keyboard and having means for operating said lever 83.

7. In a type-writing machine, the combination with a carriage and suitable letter-spacing device therefor, of a bar extending longitudinally of the carriage and pivotally supported upon the framework, key-locking device including a part mounted upon said carriage and cooperating with a projection carried upon the said pivoted bar, arm 80 projecting from said bar, link 82 loosely connecting lever 83 to said arm 80, key-lever 84 extending to the keyboard and having means for operating said lever 83, a spring for said pivoted bar, and a spring for said key-lever 84.

8. In a type-writing machine, the combination with a carriage and suitable letter-spacing device therefor, of a bar extending longitudinally of the carriage and pivotally supported upon the framework, key-locking device, including a part mounted upon said carriage and cooperating with a projection carried upon said pivoted bar, arm 80 projecting from said bar, link 82 having a slot 84 for engaging a pin projecting from said arm 80, lever 83 telescoped at one end and attached at the other end to the lower end of said link, key-lever 84 telescoped at its rear end and having a key 86 at the keyboard and having means between its ends for operating said lever 83, spring 90 for said key-lever 84, and spring 91 for said pivoted bar.

9. In a type-writing machine, the combination of a carriage, lever 80 thereon, bar 70 mounted upon the framework of the machine and op-

erated by said lever, locking-lever 78 connected to said bar 70, dog-rocker 33 having arm 72 adapted to be engaged by the lever 78, type-opening keys operatively connected to said dog-rocker, bar 60 extending longitudinally of the carriage and pivotally supported upon the framework, projection 53 adjustable along said bar 60 and engaged by said lever 65, arm 60 fixed upon said bar 60, link 59 having pin-and-slot connection with said arm 60, lever 58 attached at its rear end to said link and telescoped at its forward end, bearing-pin 66, lever 66 pivoted at its rear end and having at its forward end a key, spring 90 for said lever 66, and spring 91 for said bar 60.

10. In a front-strike writing-machine, the combination of a carriage, a platen, the detachable rod 122 supported at its outer end by the carriage and provided at its inner free end with a pressure device.

11. In a front-strike writing-machine, the combination of a carriage, a platen, the detachable spring-arm 123 attached at its outer end to the carriage and provided at its inner free end about midway of the platen with a pressure-roller 121.

12. In a type-writing machine, the combination of a platen, a deflector 94 having perforations 97 and 105 and extending down the rear side of the platen and forwardly and upwardly around the same and terminating below the printing-point, pressure-roller 96 projecting through the perforation 97 in said deflector carried by post-arm 100 having spring 101 bearing against adjustable stop-screw 104, pressure-roller 102 passing through the perforation 105 in said deflector and carried upon the forward end of arm 106, mounted independently of the arm 100, and provided with springs 110 fixed upon the carriage and bearing against said arm 106 between the ends of the latter.

13. In a type-writing machine, the combination with a platen, of a rod 118 arranged longitudinally thereover and provided with an integral flange 117, forwardly and downwardly curving arm 115 pivotally engaging said rod by means of perforated yoke 116, a spring surrounding said rod and confined in said yoke and bearing at one end upon said flange, and a pivotally-mounted paper-finger carried by the lower end of said arm and held against the platen by means of said spring.

14. In a type-writing machine, the combination with a platen, of a gage for the side edge of the paper having a downwardly and inwardly sloping face.

15. In a type-writing machine, the combination with a platen, of a gage for the side edge of the paper arranged in rear of the platen and having a downwardly and inwardly inclined face.

16. In a type-writing machine, the combination with a platen, of a rod arranged thereover, a paper-gage adjustable on said rod and comprising a rearwardly-curved arm 119 and an inclined gage 118.

17. In a type-writing machine, the combination with a platen and a paper-table arranged in rear thereof and at an angle thereto, of an adjustable paper-gage arranged in proximity to the lower end of the paper-table and in the angle between it and the rear side of the platen.

18. In a type-writing machine, the combination with a platen and a paper-table arranged in rear thereof and at an angle thereto, of a paper-gage arranged in proximity to the lower end of the paper-table and in the angle between it and the rear side of the platen, a curved arm carrying said paper-gage, and a rod arranged over the platen for supporting said arm.

19. In a type-writing machine, the combination with a platen and a deflector, of an adjustable paper-gage arranged on the rear side of the platen and between it and the deflector.

20. In a type-writing machine, the combination with a platen and a deflector, of a rod arranged over the platen, an arm adjustable on said rod and carrying rearwardly and downwardly behind the platen, and a paper-gage carried by said arm and arranged between the platen and the deflector.

21. In a type-writing machine, the combination with a platen, a paper-table and a deflector, of a paper-gage arranged in the pocket or angle formed by the paper-table and deflector and the rear side of the platen.

22. In a type-writing machine, the combination with a platen, a paper-table and a deflector, of a rod arranged over the platen, a curved arm extending down in rear of the platen, and a paper-gage carried by said arm and arranged in the angle or pocket formed by the rear side of the platen and the lower end of the paper-table and the upper end of the deflector.

23. In a type-writing machine, the combination with the platen, the paper-table and the deflector, of a rod arranged over the platen, the arm 118 adjustable on said rod and carrying a paper-guiding device, the curved arm 119 also supported on said rod and adjustable with the arm 118, and a paper-gage 110 supported by the arm 119 below the top of the platen and in rear thereof and held from the arm 118.

24. In a type-writing machine, the combination of a platen, a rod mounted over the platen, a paper-gage having a part pivotally engaging said rod and extending forwardly and downwardly around the platen, and a paper-gage arranged in rear of the platen and carried by an arm co-

acted to said paper-gage but directly engaging said rod independently of the paper-gage, the guide and the gage being adjustable together along said rod.

25. In a type-writing machine, the combination with a platen, of a rod mounted thereover, a paper-gage having a supporting portion pivotally engaging said rod and extending forwardly and downwardly around the platen, and a paper-gage arranged in rear of the platen and mounted upon a depending arm which directly engages said rod by means of ears which clamp the supporting portion of said paper-gage, the latter and the gage being adjustable together along said rod.

26. In a type-writing machine, the combination with a platen, of a rod arranged thereover and having an integral flange, a paper-gage having a perforated yoke portion pivotally engaging said rod and extending forwardly and downwardly around the platen and carrying at its lower end a pivotally-mounted paper-finger, a spring surrounding said rod and confined in said yoke and bearing at one end upon the latter and at the other end upon said flange, and a sloping paper-gage 118 arranged in rear of said platen and carried upon the lower end of a depending arm 119 which lies close to the platen and is keyed upon said rod by means of ears 120 which clamp said yoke.

27. In a type-writing machine, the combination with a carriage and a platen, of a paper-shelf having ears 129 pivotally mounted upon arms 127 which are detachably secured upon the carriage.

28. In a type-writing machine, the combination with a carriage and a platen, of a paper-shelf 126, strip 120 secured thereto and having ears 129, a ball comprising arms 127 which are mounted upon the carriage, screws 128 for pivoting said ears upon said arm, and spring 131.

29. In a type-writing machine, the combination with a carriage and a platen, of a spring-controlled paper-shelf pivotally mounted upon a device which is detachably mounted upon the carriage.

30. In a type-writing machine, the combination with a platen and a carriage, of margin-controlling device including a bar arranged in rear of the platen, a paper-shelf overhanging said bar and pivotally mounted upon a device which is detachably mounted upon the carriage, so that said paper-shelf may be swung forwardly to expose said margin-gage bar, and a spring for returning the paper-shelf to normal position.

31. In a type-writing machine, the combination with a platen and a carriage, of a support detachably mounted upon the carriage in rear of the platen, and a spring-pressed paper-shelf arranged forwardly of said support and pivotally mounted thereon.

32. In a type-writing machine, the combination of a carriage having studs, a support having forked arms which detachably engage said studs, and a spring-pressed paper-table pivotally connected to said support.

33. In a front-strike writing-machine, the combination of a carriage-plate, a platen mounted upon arm extending forwardly from said plate, a platen-rod having arms 125 upon the forward end of arm 124 secured upon said plate, and a spring for holding said plate against the platen.

34. In a front-strike writing-machine, the combination of a carriage-plate, a platen mounted in arm extending forwardly therefrom, a platen-rod hinged by arms 123 upon arm 124 projecting forwardly from said carriage-plate beneath the platen, and spring 126 mounted upon said arm 124 and bearing upon finger 127 fixed upon said arm 123.

699,797. SERIAL TYPE. PERMANENT FORM. Bridgeport, Conn. Filed Feb. 14, 1902. Serial No. 64,989. (No model.)

Claim.—1. A valve comprising an inflatable pad, a disk within said pad, a holder and arm therefor, a valve-shoe extending through said disk and holder, and a valve to close the said shoe substantially as described.

2. A valve comprising an inflatable pad, a disk within said pad, a holder in receipt of the same, a valve-shoe extending through said disk, pad and holder, means for clamping the disk, pad and holder together, and a valve to close said shoe substantially as described.

3. A valve comprising an inflatable pad, a disk within the same, a holder adapted to contain the pad and disk, a valve-shoe extending through said disk, pad and holder, means for clamping said shoe in position, a valve mounted within the pad and adapted to close the inner end of said shoe substantially as described.

699,798. VALVE FOR AUTOMATIC WATER-HEATERS. JAMES L. CHAMBER, Albany, N. Y. Filed Dec. 31, 1901. Serial No. 66,776. (No model.)

Claim.—1. In an automatic water-heater, the combination with a water-supply pipe and gas-supply pipe, of a valve comprising a casing

having a chamber therein, a diaphragm in said chamber near each end thereof, connections from the water-supply pipe to both ends of the valve-chamber outside said diaphragm, a valve for controlling the passage of the gas to the heater, and disks connected to said valve and working in said chamber adjacent to the diaphragm, whereby said diaphragm will transmit motion to said valve.

2. In an automatic water-heater, the combination with a water-supply pipe and gas-supply pipe, of a valve comprising a casing having a chamber therein connected to the gas-supply pipe, a valve-seat in said chamber, a disk valve coacting with said seat and opening toward the heater, a piston coacting with said disk and opening toward the heater, a piston connected to said valve and working in said chamber adjacent to the diaphragm, whereby said diaphragm will transmit motion to said valve, one of said pistons being of greater area than the gas-valve, and connections from the water-supply pipe to both ends of the valve-chamber outside said diaphragm, a valve for controlling the passage of the gas to the heater, and disks connected to said valve and working in said chamber adjacent to the diaphragm, whereby said diaphragm will transmit motion to said valve.

3. In an automatic water-heater, the combination with a water-supply pipe and gas-supply pipe, of a valve comprising a casing having a chamber therein connected to the gas-supply pipe, a diaphragm in said chamber near each end thereof, connections from the water-supply pipe to both ends of the valve-chamber outside said diaphragm, a valve-seat in said chamber, a disk valve coacting with said seat and opening toward the heater, and projections on said valve and having their ends lying adjacent to the diaphragm, whereby said diaphragm will transmit motion to said valve, one of said projections carrying a piston of greater area than the gas-valve, whereby when the pressure on the diaphragm is balanced the pressure of the gas will keep the valve seated.

4. In an automatic water-heater, the combination with a water-supply pipe and gas-supply pipe, of a valve comprising a casing having a chamber therein, a valve controlling the passage of gas to the heater, connections from the water-supply pipe to both ends of the valve-chamber, movable means in said chamber near each end thereof for receiving the water-pressure, and adjustable connections between said movable means and the valve, whereby said movable means will transmit motion to said valve.

5. In an automatic water-heater, the combination with a water-supply pipe and gas-supply pipe, of a valve comprising a casing having a chamber therein, movable means in said chamber near each end thereof, connections from the water-supply pipe to both ends of the valve-chamber outside said movable means, a valve for controlling the passage of the gas to the heater, stems on said valve, and heads adjustably seated to said stems and lying adjacent to diaphragm, whereby said diaphragm will transmit motion to said valve.

6. In an automatic water-heater, the combination with a water-supply pipe and gas-supply pipe, of a valve comprising a casing having a chamber therein, a diaphragm in said chamber near each end thereof, connections from the water-supply pipe to both ends of the valve-chamber outside said diaphragm, a valve for controlling the passage of the gas to the heater, disks working in said chamber adjacent to the diaphragm, and adjustable connections between said disks and the valve, whereby said diaphragm will transmit motion to the valve.

7. In an automatic water-heater, the combination with a water-supply pipe and gas-supply pipe, of a valve comprising a casing having a chamber therein connected to the gas-supply pipe, a valve-seat in said chamber, a disk valve coacting with said seat and opening toward the heater, a piston working in said chamber and connected to the valve, one of said pistons being of greater area than the gas-valve, and connections

from the water-supply pipe to both ends of the valve-chamber outside of the piston.

8. In an automatic water-heater, the combination with a water-supply pipe and gas-supply pipe, of a valve comprising a casing having a chamber therein connected to the gas-supply pipe, a diaphragm in said chamber near each end thereof, connections from the water-supply pipe to both ends of the valve-chamber outside said diaphragm, a valve-seat in said chamber, a disk valve coacting with said seat and opening toward the heater, a piston working in said chamber adjacent to the diaphragm, and connections between said piston and the valve, one of said pistons being of greater area than the gas-valve, whereby said diaphragm will transmit motion to said valve.

9. In an automatic water-heater, the combination with a water-supply pipe and gas-supply pipe, of a valve comprising a casing having a chamber therein, a diaphragm in said chamber near each end thereof, connections from the water-supply pipe to both ends of the valve-chamber outside said diaphragm, a valve for controlling the passage of gas to the heater, said valve being provided with screw-threaded stems projecting in opposite directions, disks connected to said screw-threaded stems and working in said chamber adjacent to the diaphragm, whereby said diaphragm will transmit motion to said valve, and screws extending through said disks into openings in the ends of the stems.

10. In an automatic water-heater, the combination with a water-supply pipe and gas-supply pipe, of a valve comprising a casing having a passage therethrough for the gas, a valve for controlling said passage, connections from the water-supply pipe to opposite sides of the valve for transmitting motion to said valve, a pressure-regulating valve in the water-supply pipe between the connections leading to the valve, and a supply-regulating valve in the water-supply pipe in advance of the connections leading to the valve.

11. In an automatic water-heater, the combination with a water-supply pipe and gas-supply pipe, of a valve comprising a casing having a chamber therein connected to the gas-supply pipe, a valve-seat in said chamber, a disk valve coacting with said seat and opening toward the heater, a piston connected to said valve and working in said chamber, one of said pistons being of greater area than the gas-valve, connections from the water-supply pipe to each end of the chamber outside said piston, a pressure-regulating valve in the water-supply pipe between the connections leading to the valve-chamber, and a supply-regulating valve in the water-supply pipe in advance of said connections.

12. In an automatic water-heater, the combination with a water-supply pipe and gas-supply pipe, of a valve comprising a casing having a chamber therein, a diaphragm in said chamber near each end thereof, connections from the water-supply pipe to both ends of the valve-chamber outside said diaphragm, a valve for controlling the flow of the gas to the heater, disks lying adjacent the diaphragm, adjustable connections between said disks and the valve, whereby said diaphragm will transmit motion to said valve, a pressure-regulating valve in the water-supply pipe between the connections leading to the valve-chamber, and a supply-regulating valve in said water-supply pipe in advance of said connections.

699,799. CHART FOR RECORDING ANCESTRY. CHERRMAN GULL, Providence, R. I. Filed Dec 21, 1900. Serial No. 48,708. (No model.)

Claim.—1. An improved ancestry-record, comprising a primary chart provided with a plurality of series of spaces the number of spaces in the different series increasing in geometrical progression from left to right and said series marked consecutively by numerals increasing in arithmetical progression from left to right to indicate the generation to be recorded in each series, and a series of secondary charts in number corresponding to the number of spaces in the right-hand series of the primary chart, the secondary charts having spaces arranged the same as in the primary chart, marked in increasing arithmetical progression from left to right, the left-hand space of each secondary chart being marked to indicate its corresponding right-hand space of the primary chart, and means on each secondary chart for indicating the information given in the right-hand series of the primary chart, substantially as described.

2. An improved ancestry-record, comprising a primary chart provided with a plurality of series of spaces the number of spaces in the different series increasing in geometrical progression from left to right and marked consecutively by numerals increasing in arithmetical progression from left to right to indicate the generation to be recorded in each series, and a series of secondary charts in number corresponding to the number of spaces in the right-hand series of the primary chart, the secondary charts having spaces arranged the same as in the primary chart marked in increasing arithmetical progression from left to right, the left-hand space of each secondary chart being marked the same as the right-hand space of the primary chart, the secondary charts having on their reverse sides indices, each having a series of spaces in number and on

engagement corresponding with the right-hand series of spaces on the primary chart, for indicating the name to occupy the first space on the left of each secondary chart, substantially as described.

699,800. OVERSHOE-FITTER. ROBERT E. KIM, Pittsburg, Pa. Filed Aug 2, 1901. Serial No. 73,081. (No model.)

Claim.—1. An overshoe-fitter comprising a plate adapted to be secured at the heel or back portion of an overshoe and provided with an opening therethrough, a dog adjustably mounted back of said plate and provided with a curved lower end adapted to project through the opening in the plate and engage the heel of the shoe, and means for securing said dog to the plate when in its downwardly-projected position.

2. An overshoe-fitter comprising a plate adapted to be secured at the heel or back portion of an overshoe and provided with an opening therethrough, a dog adjustably mounted back of said plate and provided with a curved lower end adapted to project through the opening in the plate and engage the heel of the shoe, said dog being provided at its upper end with two arms, one of which is adapted to yield laterally, and coacting locking means on said arm and the plate whereby said dog may be secured to the plate when in its downwardly-projected position.

3. An overshoe-fitter comprising a plate adapted to be secured at the heel or back portion of an overshoe and provided with an opening therethrough, a locking-dog adjustably mounted back of said plate and provided with a curved lower end adapted to project through the opening in the plate and engage the heel of the shoe, the lower end of said plate being bent upwardly and lying back of the lower end of said dog, and means for securing said dog to the plate when in its downwardly-projected position.

4. An overshoe-fitter comprising a plate adapted to be secured at the heel or back portion of an overshoe and provided with an opening therethrough, a dog adjustably mounted back of said plate and provided with a curved lower end adapted to project through the opening in the plate, means for securing said dog to the plate when in its downwardly-projected position, and a notched disk or screw in the heel of the shoe

with which the lower end of said dog is adapted to engage when projected downwardly.

699,801. SPRAY-POURER. ROBERT MARTIN, Paterson, N. Y. Filed Aug 18, 1901. Serial No. 73,082. (No model.)

Claim.—1. In a nozzle, the combination with a tubular body, and a spray device at one end thereof, of a cut-off sleeve mounted upon the body in cooperative relation to the spray device, and having means for directing the discharge laterally at one side only of the sleeve, also having an endwise-adjustable adjustment and a rotatable adjustment, the two adjustments being independent of each other.

2. A nozzle, comprising a tubular open-ended body, a spray device adjustable toward and away from the outer end of the body, and an endwise-adjustable cut-off sleeve mounted to slide freely upon the body into and out of engagement with the spray device, and provided with means for directing the discharge laterally at one side only of the sleeve, the latter also being capable of an inward movement under the influence of the inward adjustment of the spray device.

3. A nozzle, having a cut-off sleeve provided with means for directing the discharge laterally at one side only thereof, and also having a rotatable adjustment, and an endwise-adjustable adjustment, said adjustments being entirely independent of each other.

4. A nozzle having a spray device at one end, and a cut-off sleeve having an endwise-adjustable adjustment into and out of engagement with the spray device, and provided at its outer end with a lateral discharge-opening, the sleeve also having a rotatable adjustment which is independent of its endwise adjustment.

5. A nozzle, comprising a tubular body having a smooth exterior, and provided at one end with a spray device, and an endwise-adjustable cut-off sleeve having means to direct the discharge at one side thereof, a smooth interior embracing the body and slidable toward and away from the spray device, and a frictional engagement with the body to hold the sleeve against accidental endwise movement.

6. A nozzle, comprising a body, a spray device which is adjustable toward and away from one end thereof, and an endwise-adjustable cut-off sleeve slidably embracing the body and provided at its outer end with a partly-cylindrical cut-off flange for coadaptation with the spray device, whereby the discharge may be directed at one side only of the nozzle and the width of the discharge-opening may be varied.

7. A nozzle, having a spray device which is adjustable toward and away from one end thereof, said device being projected outwardly beyond the body and having the inner face of the projected portion provided with a marginal seat, and an endwise-adjustable cut-off sleeve mounted upon the body and provided with a partly-cylindrical flange for directing the discharge laterally at one side thereof, the outer end of the flange being adapted to fit in the marginal seat of the spray device, said sleeve also having a rotatable adjustment which is independent of its endwise adjustment.

8. A nozzle, comprising a tubular body, a spray device located externally at one end of the body and projected marginally beyond the same, the inner face of the projected portion thereof having a marginal groove formed therein, and an endwise-adjustable cut-off sleeve mounted upon the body and having its outer end provided with a longitudinally-projected cut-off flange to be received within the groove of the spray device.

9. A nozzle, comprising an open-ended tubular body having its inner end provided with a coupling, and an internal cross-bar having a screw-threaded opening, a spray-device located externally at the outer end of the body and projected marginally beyond the same, the inner face of the projected portion of the plate having a marginal groove, a central screw-threaded stem carried by the plate and adjustably received within the opening in the cross-bar, and a cut-off sleeve mounted upon the body for independent endwise and rotatable adjusting movements thereon, and provided at its outer end with a semi-cylindrical cut-off flange in coadaptation to the groove in the spray-device.

10. A nozzle, having a cut-off sleeve which is provided with means for directing the discharge laterally at one side only thereof, and also has an endwise-adjustable adjustment and a rotatable adjustment, said adjustments being entirely independent of each other and also capable of simultaneous action.

11. A nozzle, comprising a tubular body having a smooth exterior,

and provided at one end with a sprayer device, and a cut-off sleeve having means to direct the discharge at one side only thereof, and also capable of an outward-adjustable adjustment, and a rotatable adjustment which is independent of the outward adjustment, the interior of the sleeve being smooth and embracing the body with a frictional engagement to hold the sleeve against accidental movement thereon.

12. A nozzle, comprising a tubular body, the outer end of which is entirely open, a sprayer device which is normally out of engagement with the outer end of the body, whereby the discharge may be in all directions from the body as a center, and a cut-off sleeve embracing the body and having its outer end provided with a partly-cylindrical flange for engagement with the sprayer device to direct the discharge at one side only, said sleeve having an endwise adjustment to bring the flange into engagement with the sprayer device and also to withdraw the flange inwardly beyond the outer edge of the body, and also provided with a rotatable adjustment which is independent of the endwise adjustment to vary the direction of the lateral discharge.

13. A nozzle, comprising a tubular body, a sprayer device located externally thereof and adjustable toward and away from one end of the body to direct the discharge laterally in all directions from the nozzle as a center, and an endwise-adjustable cut-off sleeve having one end provided with a partly-cylindrical flange for engagement with the sprayer device to direct the discharge laterally in one direction only, said sleeve also having a rotatable adjustment which is independent of its endwise adjustment, whereby the direction of discharge may be varied and the size of the discharge-opening may be adjusted.

699,803. GASTLEY. LEON MURPHY, New York, N. Y. Filed Dec. 31, 1901. Serial No. 87,982. (No model.)

Claim.—A gas mask comprising a cuff portion of stiff material laterally folded and secured along its longitudinal free edges to normally present a cuff portion in cross-section approximately in the form of a narrow vertical oval calculated to expand when said portion is slipped over the wearer's nose and maintain a proper seal of the mask thereon, and a fitting-portion of more flexible material shown folded and longitudinally attached to present the upper continuous rounded portion, each flexible material being underlaid at the respective ends of the cuff portion and attached, a considerable part of said more flexible material extending beyond the forward end of the cuff portion to constitute a wristband which is padded and yieldingly contracted by an elastic cord.

699,808. FRUIT-GAR OPENER. MICHAEL MORGAN and FREDERICK DORRIS, DORRIS, Ill. Filed Dec. 4, 1901. Serial No. 84,846. (No model.)

Claim.—In a fruit-gar opener, the combination of two arms or levers suitably connected together whereby they may be moved toward and from

each other, each arm having a handle portion and a curved portion to substantially conform to the round top of a fruit-jar, the said curved portions having upper and lower inwardly-extending flanges and cushions confined between said flanges to grasp the sides of a jar-top, the upper flanges projecting inwardly beyond the said cushions to rest on the top of the jar in use and to insure that the pressure of the cushions will be confined to the sides of the jar at points adjacent to the top thereof, and the lower flanges projecting less than the cushions to avoid contact with the jar.

699,804. BARREL-COVER. JAMES F. MOORE, LAWRENCE, Mass. Filed Feb. 4, 1902. Serial No. 82,895. (No model.)

Claim.—A sample-holding barrel-cover comprising an annular rim portion formed to bear on the upper end of a barrel, a rim portion projecting downwardly from the outer margin of said rim, and formed to surround the upper end of the barrel, and a pin portion having a flange projecting over the inner margin of said rim and filling the space surrounded thereby, combined with an annular rim or frame seated on said flange and provided with means for detachable connection with the cover, and with a circular transparent pane covering this pin portion of the cover, the lower portion of the annular rim or frame extending between the pane and the flange of the pin portion.

699,805. BARREL-COVER. JAMES F. MOORE, LAWRENCE, Mass. Filed Mar. 17, 1902. Serial No. 83,445. (No model.)

Claim.—1. A sample-holding barrel-cover comprising an annular rim portion formed to bear on the upper end of a barrel, a rim portion projecting downwardly from the outer margin of said rim and formed to surround the upper end of the barrel, a cylindrical bottomless body portion projecting downwardly from the inner margin of the rim, and provided at its upper end with means for holding a circular transparent pane, an independent bottom piece having a marginal flange in frictional sliding contact with the body, and means for adjustably securing the flange to the body, whereby the bottom piece may be secured at different distances from the transparent pane.

2. A sample-holding barrel-cover comprising an annular rim portion formed to bear on the upper end of a barrel, a rim portion projecting downwardly from the outer margin of said rim and formed to surround the upper end of the barrel, a cylindrical bottomless body portion projecting downwardly from the inner margin of the rim, and provided at its upper end with means for holding a circular transparent pane, an independent bottom piece surrounded by the lower portion of said body and vertically adjustable therein, said bottom piece having a downwardly-projecting marginal flange in sliding contact with the interior of the body, said flange having vertical slots, and clamping-bolts engaged with the body and passing through said slots.

699,806. BOWLING AND BOWLING APPARATUS. CHARLES A. MOORE, CHICAGO, Ill. Filed Apr. 3, 1902. Renewed Sept. 28, 1901. Serial No. 73,028. (No model.)

Claim.—1. A bowling and dumping apparatus, having a supporting frame, a dumping-guide hinged in said frame and provided with guide-chains for the bowling-rope, the said rope, the bucket, and a locking device

vice which locks said guide from turning, said device adapted so to be locked by the ascending bucket, substantially as set forth.

2. A bowling and dumping apparatus, having a supporting-frame, a dumping-guide hinged in said frame and provided with guide-chains for the bowling-rope, the bucket, a locking-latch carried by said guide, a keeper mounted on the frame and adapted to be engaged by said latch, and means whereby the ascending bucket releases said latch when it enters the said guide, substantially as set forth.

3. A bowling and dumping apparatus, having a supporting-frame, a dumping-guide hinged in said frame and provided with guide-chains for the bowling-rope, the said rope, the bucket, and a locking device which locks said guide from turning, said device consisting of a keeper 16, as a fixed part of the apparatus, a locking-latch 18, pivotally mounted on the dumping-guide, and an operating-rod 19, coupled to said latch and provided with a leg 19' which extends into the path of the ascending bucket substantially as set forth.

4. A bowling and dumping apparatus, having a supporting-frame, a chain, a dumping-guide hinged in said frame, means for counterbalancing said guide yieldingly in its normal position, means for locking said guide against dumping, the bowling-rope and bucket, and means whereby the ascending bucket, when it enters said guide, unlocks the latter, substantially as set forth.

5. A bowling and dumping apparatus, having a supporting-frame, a chain, a dumping-guide hinged in said frame, means for counterbalancing said guide yieldingly, in its normal position, means for turning said guide back after dumping, guide-chains carried by said guide, a bowling-rope over said chains, a bucket means for locking said guide in its normal position during the loading of the bucket, and means actuated by the ascending bucket when it enters said guide, for releasing the latter substantially as set forth.

6. A bowling and dumping apparatus having a supporting-frame, a fitting dumping-guide in said frame, a bucket, raising and lowering means therefor and means for automatically locking the dumping-guide substantially as described.

699,807. CALCULATING-MACHINE. LEON Y. MCGOWAN and CHARLES L. RAYMOND, Rochester, N. Y. Filed June 27, 1901. Serial No. 84,388. (No model.)

Claim.—1. In a calculating-machine, a series of counting-wheels having teeth thereon, a series of pinions one engaging the teeth of each counting-wheel, said pinions having separated engaging faces P^1 , P^2 , a block for each pinion rotatable thereby and having a tooth B^1 adapted to engage intermittently teeth of the wheel of the denomination next higher than that with which the pinion engages, a leg upon said block having a loose movement between said faces P^1 and P^2 and adapted on movement of the pinion in one direction to (1) shift a movement of one tooth-space to a wheel from the wheel of next lower denomination, said block being thereby capable of movement by the wheel of higher denomination to discharge said tooth B^1 therefrom without moving the pinion, substantially as described.

2. In a calculating-machine, a series of counting-wheels having teeth thereon, a series of pinions one engaging the teeth of each counting-wheel,

a block for each pinion and rotatable thereby and having a tooth adapted to engage intermittently the teeth of the wheel of the denomination next higher than that with which the pinion engages, means for driving said block by said pinion and having a loose movement as between the pinion and block whereby said block is so moved by the counting-wheel of the higher denomination as to discharge the tooth therefrom without moving the pinion, substantially as described.

3. In a calculating-machine, a series of counting-wheels having teeth thereon, a series of pinions one engaging the teeth of each counting-wheel, said pinions having extended hubs and caskets to said hubs forming engaging faces P^1 , P^2 , a block for each pinion and rotatable thereby and having a tooth B^1 adapted to engage the teeth of the wheel of the denomination next higher than that with which the pinion engages, a leg upon said block having a loose movement between said faces P^1 , P^2 , said pinions and blocks being driven on the same axis whereby on operating the wheel of lower denomination to a selected extent, the movement is transmitted through the block to the wheel of next higher denomination, and on operating said wheel of next higher denomination the block turns and discharges said tooth from said wheel by the movement of the leg in said casket and said pinion when moved, substantially as described.

699,808. MOTOR-VEHICLE. WILLIAM BURNER, Preston, England, assignor to T. Gifford & Company, Limited, Preston, England. Filed July 2, 1901. Serial No. 84,383. (No model.)

Claim.—1. In motor-propelled vehicle an improved yielding bearing comprising a divided sleeve, a flange formed on the sleeve, a divided ring of plane-convex longitudinal sections loosely fitting around the sleeve, a supporting-bracket and cover, a concave recess formed around the inside of the bracket and cover corresponding to the convex surface of the divided ring which bears in said recess, and a flexible ring placed between the bracket and flange around the divided sleeve, whereby slight movement of the shaft in a vertical plane and laterally may occur, substantially as described.

2. In a motor-vehicle, an improved spring-drive consisting of two springs coiled in opposite directions one end of each spring being attached to the shaft carrying the chain-wheels and other end of each spring being secured to the compensating gear, whereby shocks from the road-wheels are prevented from being transmitted to the motor when running in a forward or backward direction, substantially as described.

3. In a motor-vehicle, an improved spring-drive consisting of two sets of coiled springs, each set comprising two coiled springs arranged one within the other but coiled in opposite directions, one end of

each spring in the two sets being attached in the compensating gear, and the other end of each spring being attached in the shaft carrying the chain-wheel, substantially as described.

4. In a motor-propelled vehicle, an improved spring-drive, comprising a spiral spring having one end attached to the compensating gear-wheel and the other to the shaft carrying the chain-wheel, a circular rim formed on the gear-wheel thereby inducing the spring, substantially as described.

5. In a motor-vehicle, an improved arrangement of compensating gearing and shafting, comprising a "jack-in-the-box" gearing mounted loosely upon a main shaft, a chain-wheel carried by the shaft on one side of the compensating gearing a sleeve extending over the shaft on the other side of the compensating gearing, said shaft projecting somewhat beyond the sleeve, a clutch sliding on this projecting portion of the shaft, a chain-wheel carried by the sleeve, clutch-jaws formed on the chain-wheel, spring-connections between the "jack-in-the-box" gearing and both the shaft and the sleeve, substantially as described.

6. In a motor-vehicle, in combination with a compensating gear-shaft and sleeve operated by "jack-in-the-box" gearing, a clutch comprising a sleeve sliding upon the main gear-shaft, a collar formed on the sleeve, a feather on the shaft and corresponding keyway on the sleeve, clutch-teeth formed on the face of the sleeve adapted to engage with recesses in the chain-wheel, a finger-bracket secured to the end of the shaft, a spring-controlled latch loosely supported by the finger-bracket, whereby the clutch may be held in or out of gear with the chain-wheel substantially as described.

7. In a motor-propelled vehicle, in combination with a road-wheel, a chain-wheel having a central cyphers fitting over the hub of the road-wheel, arms carried by the chain-wheel, said arms being attached to the rim of the road-wheel whereby the power of the motor is transmitted directly to the rim of the wheel, substantially as described.

699,809. SIGAR-PERFORATING MACHINE. ERIC P. FRANKS.
Brooklyn, Mass. Filed Sept. 11, 1901. Serial No. 78,071. (No model.)

Claim.—In a cigar-perforating machine, the combination, with a base-plate provided with a channel having a pointed end portion, of a longitudinally-adjustable guide provided with a notched finger which projects longitudinally from its lower part over the pointed end portion of the said channel and engages with the tip of the sign, and a plunger provided with a perforator and sliding vertically in the said guide over the pointed end portion of the said channel, substantially as set forth.

699,810. CHAIR. ARTHUR J. FROST, Henderson, Tenn. Filed May 21, 1901. Serial No. 61,200. (No model.)

Claim.—1. In combination with a chair provided with adjustable back and foot sections, a rotatable supporting frame, vertically-disposed

supporting members, suitable connections between the lower portions of said members and the body of the chair, substantially horizontally disposed members crossing and pivotally secured to said vertically-disposed members, and suitable connections between the respective ends of the horizontally-disposed members and the back and foot sections, substantially as described.

2. A reclining-chair comprising suitable side-supporting members, a seat-section, pivoted back and foot sections, and means for adjusting the back and foot sections simultaneously comprising an elongated rod, means for pivotally supporting the rod intermediate of its ends, a link connection between one end of said rod and the back-section, a corresponding link connection between the opposite end of the rod and the foot-section, and means for adjusting the length of the several link connections, substantially as described.

3. In combination with a reclining-chair provided with pivoted back and foot sections, means for adjusting said sections comprising a connecting-bar pivoted intermediate of its ends, pivotal connections between said bar and the respective sections, a rack on the connecting-bar, a dog adapted to engage said rack under normal conditions, and means for disengaging the dog from the rack comprising an operating-cable passing through an opening in the chair within convenient reach of an operator and connected at its ends to the free end of the dog, and a guide on the connecting-bar for said cable, substantially as described.

4. In combination with a reclining-chair provided with pivoted back and foot sections, means for adjusting said sections comprising a pivoted connecting-bar, link connections between the ends of the connecting-bar and the respective sections, a toothed rack on the lower surface of the connecting-bar, a pivoted dog adapted to engage said rack to lock the sections in adjusted position, and a spring between the free end of the dog and a portion of the connecting-bar, substantially as described.

5. In combination with a reclining-chair provided with suitable side supports and adjustable back and foot sections, a brace-rod connecting the side frames, and means for adjusting the sections comprising suitable brackets extending above and below the upper and lower edges of the brace-rod, an elongated connecting-rod pivotally secured in the upper extensions of the brackets, link connections between the ends of the connecting-rod and the back and foot sections respectively, a toothed rack on the lower surface of the connecting-rod, a dog adapted to engage said rack pivoted in the lower extension of the brackets, and a spring between the free end of the dog and a portion of the connecting-rod, substantially as and for the purpose described.

6. In combination with a chair provided with adjustable back and foot sections, substantially vertically disposed supporting members, substantially horizontally disposed members pivoted intermediate of their ends to said vertical members, and suitable connections between the respective ends of the horizontally-disposed members and the back and foot sections.

699,811. SHOW-CASE. FREDERICK POLLARD, Cleveland, Ohio.
Filed June 12, 1901. Serial No. 64,302. (No model.)

Claim.—1. A show-case of the character indicated, comprising a base *d*, an upright glass front or front plate *a*, upright glass sides or end plates *b* and *b'*, a back *c*, and a glass top or top plate *e* mounted upon the upright plates and provided, in its under side, with a groove *f* which extends between the side or end plates near the forward edge of the top plate, and the front plate *a* extending, at the top, into and from end to end of the said groove *f*, and being cut away next to its side edges to accommodate the extension of the front plate in under the top plate and beyond the ends of the said groove *f* in the said top plate.

2. A show-case of the character indicated, comprising a base *d*, an upright glass front or front plate *a*, upright glass sides or end plates *b* and *b'*, a back *c*, and a glass top or top plate *e* mounted upon the upright plates and provided, in its under side, with a groove *f* which extends between the side or end plates near the forward edge of the top plate and has its ends sloping inwardly and upwardly, and the front plate *a* extending, at the top, into and from end to end of the said groove *f*, and being cut away next to its side edges to conform to the aforesaid sloping end walls of the aforesaid groove *f* and to accommodate the extension of the front plate in under the top plate and beyond the ends of the said groove *f* in the said top plate.

3. A show-case of the character indicated, comprising a base *d*, an upright glass front or front plate *a*, upright glass sides or end plates *b* and *b'*

overlapping and extending forwardly beyond opposite side edges, respectively, of the front plate and having grooves *f'* engaging the said edges of the front plate, and a glass top or top plate *e* mounted upon the said upright plates and provided, in its under side, with a groove *f* which extends between the side or end plates near the forward edge of the said top plate, and the front plate *a* extending, at the top, into and from end to end of the said groove *f* and being cut away, next to its side edges, to accommodate the extension of the front plate in under the top plate into the aforesaid grooves *f'* of the side or end plates beyond the ends of the groove *f* in the said top plate.

4. A show-case of the character indicated, comprising a base *d*, an upright glass front or front plate *a*, upright glass sides or end plates *b* and *b'* overlapping and extending forwardly beyond opposite side edges, respectively, of the front plate, and a glass top or top plate *e* mounted upon the upright plates and provided, in its under side over the side or end plates, with grooves *f'* which extend from the front plate rearwardly, and the side or end plates extending, at the top, into and from end to end of the said grooves *f'* and being cut away to accommodate the extension of the said side or end plates in under the top plate forwardly beyond the side edges of the front plate.

699,813. STEAM-BOILER. CHARLES B. BRADLEY, New York.
N. Y. Filed Oct. 21, 1900. Serial No. 734,514. (No model.)

Claim.—1. In a steam-boiler, the combination of a series of upper headers, a steam and water drum, one or more connecting-passages from each of the said headers to the side of the said drum, and one or more downflow-passages leaving the lower side of each steam and water drum, said downflow-passages or passages extending along the drum substantially the same portion of its length as do the passages from the headers, as and for the purpose set forth.

2. In a steam-boiler, the combination of a steam and water drum as an upper header, one side thereof adjoining the said drum and in communication therewith, and one or more downflow-passages leaving the lower side of each steam and water drum, each downflow passage or passage extending along the drum substantially the same portion of its length as does the upper header, as and for the purpose set forth.

3. In a steam-boiler, the combination of a steam and water drum, two or more headers, connecting-passages between each header and drum, and main downflow-pipes leaving the steam and water drum from the lower side thereof at intervals along its length, there being one or more such downflow-pipes for each header, as and for the purpose set forth.

4. In a steam-boiler, the combination of a steam and water drum, an inclined header, one or more passages, normally water-filled, connecting said header and each drum, and one or more rise-passages leaving the upper side of said header and entering the steam and water drum and terminating at a point above the water-line therein.

5. In a steam-boiler, the combination of a steam and water drum, a horizontal or horizontally-inclined header, one or more passages, normally water-filled, connecting said header to each drum, and one or more rise-

passages leaving the upper side of each header and entering the steam and water drum and terminating at a point above the water-line therein.

6. In a steam-boiler, the combination of a steam and water drum, a series of horizontal or horizontally-inclined headers, one or more passages, normally water-filled, connecting each header to said drum, and one or more rise-passages leaving the upper side of each of such headers and entering the steam and water drum and terminating at a point above the water-line therein.

7. In a steam-boiler, the combination of a steam and water drum, a header, passages normally water-filled, connecting each header and drum, and a series of rise-passages from the upper side of said header, each rise-passages entering the said drum above the water-line and extending laterally beyond the inside of the shell of same.

8. In a steam-boiler, the combination of a steam and water drum, one or more headers, passages, normally water-filled, connecting each drum and header, and one or more rise-passages from the upper side of each of the said headers, each rise-passages entering the said drum above the water-line and extending laterally beyond the inside of the shell of same.

9. In a steam-boiler, the combination of a steam and water drum, a header, passages, normally water-filled, connecting each header and drum, and rise-passages from the upper side of said header, each rise-passages entering the said drum and terminating at a point above the water-line therein with the exit ends of same pointing downward.

10. In a steam-boiler, the combination of a steam and water drum, a series of headers, passages, normally water-filled, connecting each drum and header, and one or more passages from the upper side of each of the said headers, each rise-passages entering the said drum and terminating at a point above the water-line therein with the exit ends of same pointing downward.

11. The combination of one or more upper headers, a steam and water drum, passages, normally water-filled, connecting said header or headers and each drum, one or more downflow-passages from the lower side of each steam and water drum, and one or more rise-passages from the upper side of said header or headers, each rise-passages entering the steam and water drum and terminating at a point above the water-line therein.

12. In a steam-boiler, the combination of a steam and water drum, a header or headers, passages, normally water-filled, connecting said header or headers and each drum, downflow-pipes leaving the lower side of said steam and water drum at intervals along its length, and rise-passages from the upper side of said header or headers, each rise-passages entering the said drum and terminating at a point above the water-line therein.

13. In a steam-boiler, comprising banks of vertical or vertically-inclined tubes, terminating in upper and lower headers, a space left open and free between two adjacent headers, of width at least as great as the diameter of the tubes, each space, in the headers on each side of the inverted V, being opposite each other, and removable covers or plugs inserted in each space, between each adjacent header, separated by each space, as and for the purpose set forth.

14. In a steam-boiler, comprising banks of vertical or vertically-inclined tubes, two or more top headers connecting with the upper ends, and one or more bottom headers connecting with the lower ends of such tubes, with a space or spaces left open and free between the said top headers, and removable covers for each open space as and for the purpose set forth.

15. In a steam-boiler, comprising two sets or banks of vertically-inclined tubes together forming an inverted V and each set or bank of tubes terminating in upper and lower headers, a space left open and free between two adjacent headers of each set or bank of tubes, of width at least as great as the diameter of the tubes, each space, in the headers on each side of the inverted V, being opposite each other, and removable covers or plugs inserted in each space, between each adjacent header, separated by each space, as and for the purpose set forth.

699,818. PLAYING-BALL. FRANK H. RICHARDS, Hartford, Conn., assignor to the Knapp Manufacturing Company, a Corporation of New Jersey. Filed Feb. 7, 1900. Serial No. 68,001. (No model.)

Claim.—1. In a playing-ball, a spherical shell consisting at least partially of celluloid, said shell being distended by plastic material injected thereinto.

2. In a playing-ball, a shell formed at least partially of celluloid, said shell being distended by a core of gata-pieces injected thereinto.

3. In a playing-ball, an embossed hard shell formed of plastic material and distended by a core of plastic material injected therewith.
4. In a playing-ball, an embossed shell formed of celluloid and distended by a gutta-percha core injected therewith, and a plug filling the injection-hole in the shell.
5. A playing-ball comprising a cushion or continuous embossed hard shell of plastic material distended by a core of plastic material injected therewith.
6. In a playing-ball, a cushion or continuous shell of celluloid distended by a mass of mobile material injected therewith.
7. In a playing-ball, an embossed shell of plastic material distended by a core of plastic material injected therewith, said shell being harder than said core.
8. In a playing-ball, a shell distended by a core injected therewith, one of said shell and core elements consisting of celluloid and the other consisting of gutta-percha.

699,814. MACHINE FOR MAKING BATTERY-GRIDS. WILLARD F. EMMERICH, Buffalo, N. Y., assignor to Great Storage Battery Company, New York, N. Y., a Corporation of West Virginia. Filed Oct. 2, 1900. Serial No. 38,177. (No model.)

- Claim.—1. In a machine for making battery-grids, the combination with a pair of upright spinning-rollers, of an upright support for the blank or battery-plate arranged to move back and forth between said rollers, substantially as set forth.
2. The combination with a pair of upright horizontally-rotating frames, of upright spinning-rollers journaled in said frames, means for moving said frames toward and from each other, and an upright support for the blank or battery-plate arranged to reciprocate between said rollers, substantially as set forth.
3. In a machine for making battery-grids, the combination with a pair of frames which are movable toward and from each other, of spinning-rollers journaled in said frames, toggles which connect said frames with a stationary part of the machine, and means for actuating said toggles, substantially as set forth.
4. The combination with a pair of horizontally-rotating frames and upright spinning-rollers journaled therein, of horizontal toggles connecting said frames with a stationary part of the machine, means for straightening and deflecting said toggles, and a support for a blank arranged to reciprocate between said rollers, substantially as set forth.
5. The combination with a pair of horizontally-rotating frames and upright spinning-rollers journaled therein, of horizontal toggles connecting said frames with a stationary part of the machine, a transverse rock-shaft having actuating-arms, and rods connecting said toggles with said actuating-arms, substantially as set forth.
6. The combination with a pair of horizontally-rotating frames and upright spinning-rollers journaled therein, of horizontal toggles connecting said frames with a stationary part of the machine, a transverse rock-shaft

- having actuating-arms, connections between said toggles and said actuating-arms, and a pressure device applied to said rock-shaft for holding the spinning-rollers to their work with a yielding pressure, substantially as set forth.
7. The combination with a pair of horizontally-rotating frames and upright spinning-rollers journaled therein, of horizontal toggles connecting said frames with a stationary part of the machine, a transverse rock-shaft having actuating-arms and a pressure arm or lever, connections between said toggles and said actuating-arms, and a movable weight mounted on said pressure-arm, substantially as set forth.
8. The combination with a pair of horizontally-rotating frames and upright spinning-rollers journaled therein, of horizontal toggles connecting said frames with a stationary part of the machine, a transverse rock-shaft having actuating-arms connected with said toggles and a pressure-lever which extends in front and in rear of said rock-shaft, a weight arranged to move lengthwise on said pressure-lever, and an adjusting device for shifting said weight on said lever, substantially as set forth.
9. The combination with a pair of horizontally-rotating frames and upright spinning-rollers journaled therein, of horizontal toggles connecting said frames with a stationary part of the machine, a transverse rock-shaft having a pressure-lever and actuating-arms connected with said toggles, a movable weight carried by said pressure-lever, and a longitudinal adjusting-curve for said weight mounted on said lever, substantially as set forth.
10. The combination with a pair of horizontally-rotating frames and upright spinning-rollers journaled therein, of horizontal toggles connecting said frames with a stationary part of the machine, a transverse rock-shaft having a pressure-lever and actuating-arms connected with said toggles, a movable weight carried by said pressure-lever, a rotary adjusting-curve mounted lengthwise on said lever and held against longitudinal movement therein, and a shifting nut traversing said curve and connected with said weight, substantially as set forth.
11. In a machine for making battery-grids, the combination with the spinning-rollers and a frame or carrier arranged to reciprocate between said rollers, of a blank-holder capable of longitudinal adjustment in said carrier, substantially as set forth.
12. In a machine for making battery-grids, the combination with the spinning-rollers and a frame or carrier arranged to reciprocate between said rollers, of a blank-holder movable lengthwise in said carrier, and an adjusting-curve for shifting said holder in said carrier, substantially as set forth.
13. In a machine for making battery-grids, the combination with the spinning-rollers, of a frame or carrier arranged to reciprocate between said rollers and provided with a pointer, of a blank-holder capable of longitudinal adjustment in said carrier, a gauge-bar secured to said holder and traversing said pointer, and means for adjusting the holder in said carrier, substantially as set forth.
14. The combination with a pair of movable frames and spinning-rollers journaled therein, of a rock-shaft, connections between said rock-shaft and said frames for moving the same toward each other, and a pressure device applied to said rock-shaft for holding the spinning-rollers to their work with a yielding pressure, substantially as set forth.
15. The combination with a pair of movable frames and spinning-rollers journaled therein, of toggles connecting said frames with a stationary part of the machine, a rock-shaft having actuating-arms, connections between said arms and said toggles, and a pressure device applied to said rock-shaft for holding the spinning-rollers to their work with a yielding pressure, substantially as set forth.
16. The combination with a movable frame and a spinning-roller journaled therein, of a pressure device, and mechanism connecting said movable frame and said pressure device whereby said spinning-roller is held with a pressure to its work and is automatically moved away from the work, substantially as set forth.

699,815. RING-COVER. WILLIAM J. BROWN, Kingston, N. Y. Filed Dec. 14, 1901. Serial No. 38,187. (No model.)

- Claim.—A ring-cover, consisting of handle *a*, adapted to be held vertically when in use, shaft *b*, curved through substantially a right angle, and a cutting blade or blades *c*, projecting downward from said shaft at or near its extremity in a direction parallel with the axis of the handle, the bottom cutting edges being transverse to said shaft, for covering the ring of meat to a uniform depth preparatory to cooking, substantially as specified.

699,816. FENCE. LOUIS H. BARTON, Albany, N. Y. Filed Nov. 26, 1901. Serial No. 38,171. (No model.)

- Claim.—In a fence, the combination with means, of a stay consisting of a single piece of wire twisted at one end around the second runner and extended therefrom to the top runner and then downward to the bottom runner to form a top loop and to provide lower connecting portion, the upper terminal of the wire being twisted around the loop at the lower end thereof, and the said wire being twisted around the runner below the second and called to form upon the runner the lower connecting portion, and the reinforcing end or brace passing through the said loop and secured to the adjacent runner by the stay and extending from the bottom of the fence to the second runner, substantially as described.

699,817. WATER-PROOF FENCING FOR ELECTRIC LIGHTS. FRANK J. BROWN, New York, N. Y. Filed Feb. 10, 1900. Serial No. 38,188. (No model.)

- Claim.—1. The combination of a casing, of substantially conical shape internally, formed with an end disk to which is secured an electric terminal-block and lamp-socket, an annular gasket on the inner side of said end disk, a substantially cylindrical transparent shield closed at one end, the edges of the other end resting against said annular gasket, a stop for straddling the closed end of the transparent shield, means for pressing and holding the said stop against the said transparent shield, and a cover connected with the casing and adapted to lockup and protect the parts within the casing, together with means for securing the said cover in position, substantially as set forth.
2. The combination of a casing, of substantially conical shape internally, formed with an end disk to which is secured the electric terminal-block and lamp-socket, an annular gasket on the inner side of said end disk, a substantially cylindrical transparent shield closed at one end, the edges of the other end resting against said annular gasket, a stop for straddling the closed end of the transparent shield, means for pressing and holding the said stop against the said transparent shield, and a cover formed of an open grating connected with the casing and adapted to lockup and protect the parts within, together with means for securing the said cover in position, substantially as set forth.
3. The combination of a casing, of substantially conical shape internally, formed with an end disk to which is secured an electric terminal-block and lamp-socket, an annular gasket on the inner side of said end disk, a substantially cylindrical transparent shield formed with a closed hemispherical end, the edges of the other open end resting against said annular gasket, a stop for straddling the closed hemispherical end of the transparent shield, said stop being made in two sections loosely connected together, one section of which is pivotally connected to the casing below the position of the hemispherical end of the transparent shield for the purpose of pressing the stop against the shield to effect a water-tight joint between the latter and the casing, substantially as set forth.

the edges of the other end resting against said annular gasket, a stop for straddling the closed end of said transparent shield, said stop being pivotally connected to the casing, and means for pressing and holding the said stop against the said transparent shield for the purpose of effecting a water-tight joint between the shield and the casing, substantially as set forth.

4. The combination of a casing, of substantially conical shape internally, formed with an end disk to which is secured an electric terminal-block and lamp-socket, an annular gasket on the inner side of said end disk, a substantially cylindrical transparent shield closed at one end, the edges of the other end resting against said annular gasket, a stop for straddling the closed end of said transparent shield, said stop being pivotally connected to the casing, and a cover passing through said casing and bearing against said stop and holding said transparent shield against the said gasket to form a water-tight joint, substantially as set forth.

5. The combination of a casing, of substantially conical shape internally, formed with an end disk to which is secured an electric terminal-block and lamp-socket, an annular gasket on the inner side of the said end disk, a substantially cylindrical transparent shield, formed with a closed hemispherical end and having the edges of the other end resting against said annular gasket, a stop for straddling the closed hemispherical end of the transparent shield, said stop being pivotally connected to the casing below the position of the hemispherical end of the transparent shield for the purpose of pressing the stop against the shield to effect a water-tight joint between the latter and the casing, substantially as described.

6. The combination of a casing, of substantially conical shape internally, formed with an end disk to which is secured an electric terminal-block and lamp-socket, said end disk being formed with an external flange-chamber, an annular gasket on the inner side of said end disk, a substantially cylindrical transparent shield, closed at one end, the edges of the other end resting against said annular gasket, a stop for straddling the closed end of said transparent shield, and means for pressing and holding the said stop against the transparent shield for the purpose of effecting a water-tight joint between the shield and the casing, substantially as set forth.

7. The combination of a casing, of substantially conical shape internally, formed with an end disk to which is secured an electric terminal-block and lamp-socket, said end disk being formed with an external flange-chamber, provided with a removable water-tight cover, an annular gasket on the inner side of said end disk, a substantially cylindrical transparent shield formed with one open end and one closed end, the edges of the open end resting against said annular gasket, a stop for straddling the closed end of said transparent shield, and means for pressing and holding the said stop against the transparent shield, for the purpose of effecting a water-tight joint between the shield and the casing, substantially as set forth.

8. The combination of a casing, of substantially conical shape internally, formed with an end disk to which is secured an electric terminal-block and lamp-socket, an annular gasket on the inner side of said end disk, a substantially cylindrical transparent shield closed at one end, the edges of the other end resting against said annular gasket, a stop for straddling the closed end of the transparent shield, means for pressing and holding the said stop against the said transparent shield, and a cover connected with the casing and adapted to lockup and protect the parts within the casing, together with means for securing the said cover in position, substantially as set forth.

9. The combination of a casing, of substantially conical shape internally, formed with an end disk to which is secured an electric terminal-block and lamp-socket, an annular gasket on the inner side of said end disk, a substantially cylindrical transparent shield closed at one end, the edges of the other end resting against said annular gasket, a stop for straddling the closed end of the transparent shield, means for pressing and holding the said stop against the said transparent shield, and a cover formed of an open grating connected with the casing and adapted to lockup and protect the parts within, together with means for securing the said cover in position, substantially as set forth.

10. The combination of a casing, of substantially conical shape internally, formed with an end disk to which is secured an electric terminal-block and lamp-socket, an annular gasket on the inner side of said end disk, a substantially cylindrical transparent shield formed with a closed hemispherical end, the edges of the other open end resting against said annular gasket, a stop for straddling the closed hemispherical end of the transparent shield, said stop being made in two sections loosely connected together, one section of which is pivotally connected to the casing below the position of the hemispherical end of the transparent shield for the purpose of pressing the stop against the shield to effect a water-tight joint between the latter and the casing, substantially as set forth.

669,818. VALVE. JAMES J. STANLEY, Wilkes, Pa., assignor to Remond Valve Manufacturing Company, Remond, Pa., a Corporation of Pennsylvania. Filed Aug. 9, 1891. Serial No. 71,008. (No model.)

Claim.—1. The combination of a rotary plug-valve, a body in which said valve is fitted to seat and turn, and which is subdivided peripherally except by lateral pipe connections, an inclined cam-face formed on one end of the valve-body, in position to limit the traverse of the valve in one direction, and a locking device connected to the end of the valve which adjusts the cam-face, said locking device being freely movable throughout the middle portion of its traverse and abutting against the cam-face adjacent to one of the limits of said traverse.

2. The combination of a valve, a body in which said valve is fitted to seat and turn, oppositely-inclined cam-faces formed on the exterior of the valve-body adjacent to one end of the valve-rod, and a locking device rotatably with the valve and abutting against one of said cam-faces in the open and in the closed positions of the valve.

3. The combination of a valve, a body in which said valve is fitted to seat and turn, two oppositely-inclined cam-faces formed on the exterior of the valve-body adjacent to one end of the valve-rod, and a locking-collar rotatably with the valve and having opposite locking arms or dogs, each abutting against one of the cam-faces of each pair in the open and in the closed positions of the valve.

4. The combination of a valve, a body in which said valve is fitted to seat and turn, two oppositely-inclined cam-faces formed on the exterior of the valve-body adjacent to one end of the valve-rod, an indexing projection interposed between said cam-faces, and a locking device rotatably with the valve and abutting against one of said cam-faces in the open and in the closed positions of the valve.

669,819. HOPPER-CAR AND DOOR THEREOF. RALPH V. RAGG, Westmont, Pa. Filed Dec. 20, 1891. Serial No. 64,328. (No model.)

Claim.—1. A hopper-car provided with a bottom sloping longitudinally from the side toward the transverse middle line of the car, said

bottom also sloping transversely from the side toward the longitudinal middle line of the car, a cross-section of said transverse slopes having the form of a V.

2. In a hopper-car, a bottom sloping downwardly from both ends, and from both sides in a V shape toward the center, supports and braces secured to the lower ends of said bottom and attached to the adjoining portions of the car construction.

3. In a hopper-car, a bottom sloping downwardly toward the center from both ends, and from both sides in a V shape, supports and braces secured to said bottom and to the adjoining portions of the car construction, said supports and braces being also connected to the floor-framing by intermediate braces.

4. A hopper-car provided with a bottom sloping both longitudinally and transversely toward the center, a cross-section of the transverse slopes having the form of a V and a central incline sloping downwardly in both directions toward the ends.

5. A hopper-car provided with a bottom sloping both longitudinally and transversely toward the middle line of the car, a central transverse incline sloping downwardly in both directions from the center of the car toward the ends, and a longitudinal central ridge extending downwardly about the central framing, thus forming four compartments at the lower portion of the hopper.

6. In a hopper-car provided with a bottom sloping both longitudinally and transversely toward the center of the car and forming trapezoidal openings at the lower portion thereof, doors of trapezoidal shape adapted to cooperate with said openings.

7. In a hopper-car provided with a bottom sloping both longitudinally and transversely toward the center thereof, doors of trapezoidal form adapted to cooperate with corresponding openings in the lower part of the hopper-bottom, the adjacent doors on each side of the transverse center line being moved together in pairs by a connecting member.

8. A hopper-car provided with a bottom sloping transversely toward the center, doors of trapezoidal form adapted to cooperate with corresponding openings in said bottom, said doors being attached together in pairs by a connecting member, and operating mechanism attached to said connecting member intermediate of said doors for closing and releasing the same.

9. A hopper-car having a bottom sloping both longitudinally and transversely in a downward direction toward the center of said car and forming trapezoidal openings at the lower portion thereof, doors of trapezoidal form hinged to a horizontal support and arranged with their deeper ends adjacent, said doors being adapted to cooperate with the openings above.

10. In a hopper-car provided with a bottom sloping both longitudinally and transversely toward the center and forming trapezoidal openings at the lower ends thereof, hinged doors of trapezoidal form adapted to cooperate with the openings above, said doors being moved together in pairs by a connecting member to the intermediate portion of which operating mechanism is attached.

11. A hopper-car provided with a bottom sloping both longitudinally and transversely toward the center, a central transverse incline sloping downwardly in both directions from the center, said bottom having trapezoidal openings at the lower portion thereof, hinged trapezoidal doors arranged in pairs and adapted to cooperate with the openings above.

12. A hopper-car provided with a bottom sloping both longitudinally and transversely toward the center, a central transverse incline sloping downwardly in both directions from the center, said bottom having trapezoidal openings at the lower portion thereof, hinged doors of trapezoidal form, said doors being moved together in pairs by a connecting member and adapted to cooperate with the openings above.

13. A hopper-car provided with a bottom sloping both longitudinally and transversely toward the center, a central transverse incline sloping downwardly in both directions from the center, said bottom having trapezoidal openings at the lower portion thereof, hinged doors of trapezoidal form, said doors being moved together in pairs by a connecting member to the intermediate portion of which operating mechanism is attached.

14. A hopper-car provided with a bottom sloping both longitudinally and transversely toward the center, a central transverse incline sloping downwardly in both directions from the center, a central longitudinal ridge sloping downwardly in both directions toward the ends, said bottom having trapezoidal openings at the lower portion thereof, hinged trapezoidal doors arranged in pairs and adapted to cooperate with the openings above.

15. A hopper-car provided with a bottom sloping both longitudinally and transversely toward the center, a central transverse incline sloping downwardly in both directions from the center, a central ridge sloping downwardly in both directions toward the ends, thus forming four compartments at the lower portion of said hopper each of which compartments is provided with a trapezoidal opening at the lower portion thereof.

hinged doors of trapezoidal form arranged in pairs and adapted to cooperate with the openings above.

16. A hopper-car provided with a bottom sloping both longitudinally and transversely toward the center, a central transverse incline sloping downwardly in both directions from the center, a central longitudinal ridge sloping downwardly in both directions toward the ends, thus forming four compartments at the lower portion of said hopper, each of which compartment is provided with a trapezoidal opening at the lower portion thereof, hinged doors of trapezoidal form moved together in pairs by a connecting member and adapted to cooperate with the trapezoidal openings of the doors.

17. A hopper-car provided with a bottom sloping both longitudinally and transversely toward the center, a central transverse incline sloping downwardly in both directions from the center, a central longitudinal ridge, thus forming four compartments at the lower portion of said hopper each of which is provided with a trapezoidal opening at the lower portion thereof, hinged doors of trapezoidal form moved together in pairs by a connecting member, and operating mechanism connected to said member intermediate of the doors.

18. A hopper-bottom car provided with trapezoidal doors moved together in pairs by a connecting member, and mechanism for operating the same intended to said member intermediate of said doors.

19. A hopper-bottom car provided with hinged trapezoidal doors arranged with their deeper ends adjacent and moved together in pairs by a connecting member attached thereto, and operating mechanism connected to said member intermediate of said doors.

20. A hopper-bottom car provided with trapezoidal doors moved together in pairs by a connecting member, the deeper ends of said trapezoidal doors being adjacent, a chain attached to said member intermediate of the doors above, and means for operating said chain.

21. A hopper-bottom car provided with a pair of trapezoidal doors arranged with their deeper ends adjacent, said doors being moved together by a connecting member attached thereto, a chain connected to said member intermediate of said doors, a shaft for winding said chain and means for operating and locking said shaft.

669,820. DOOR FOR DUMPING-CAR. RALPH V. RAGG, Westmont, Pa. Filed Dec. 11, 1891. Serial No. 64,400. (No model.)

Claim.—1. In a dumping-car, a door mounted on swinging links, an endless flexible member secured to said door, and means for operating the same to open and close the door above.

2. In a dumping-car, a pair of adjacent doors mounted on swinging links, a connecting member secured to each of said doors, an endless flexible member attached to said connecting member intermediate of said doors, and means for operating the same.

3. In a dumping-car, a pair of doors mounted on swinging links, a connecting member secured to each of said doors, an endless flexible member

secured to said connecting member intermediate of the doors, a winding-shaft and pulley for operating said flexible member for the purpose of opening and closing said doors.

4. In a dumping-car, a pair of doors mounted on swinging links, a connecting member secured to each of said doors, an endless flexible member attached to said connecting member intermediate of the doors, an idler-pulley mounted above said doors, and a winding-shaft for operating said flexible member to open and close the doors above.

5. In a dumping-car, a pair of doors mounted on swinging links, a connecting member secured to each of said doors, an endless flexible member attached to said connecting member intermediate of the doors, an idler-pulley mounted above said doors, an operating-pulley mounted on a winding-shaft, and means for locking said winding-shaft.

6. In a dumping-car, provided with center shaft, a pair of doors mounted on swinging links, a connecting member secured to each of said pair of doors, an endless flexible member secured to said connecting member intermediate of said doors, means for operating said flexible member comprising an idler-pulley, an operating-pulley and a winding-shaft, said operating mechanism being located in an open space between and below the center shaft of the car.

7. In a dumping-car, a pair of doors mounted on swinging links, a connecting member secured to each of said doors, an endless flexible member attached to said connecting member intermediate of the doors, an idler-pulley mounted on the car-frame above said doors, an operating-pulley mounted on a winding-shaft provided with a ratchet, a pawl and a pawl-lock.

8. In a dumping-car, a pair of doors mounted on swinging links, a connecting member secured to each of said doors, a sprocket-chain attached to the connecting member intermediate of said doors, an idler-pulley mounted on the car-frame above said doors, a sprocket-wheel and winding-shaft for opening and closing the doors by means of the chain above.

9. In a dumping-car, a pair of doors, swinging links pivoted to said doors and to the car-frame, a connecting member attached to each of said doors, a sprocket-chain attached to said connecting member intermediate of the doors, an idler-pulley mounted on the car-frame above said doors, a sprocket-wheel and winding-shaft thereto, said winding-shaft being provided with a ratchet, pawl and pawl-lock.

10. A car provided with a pair of hoppers extending below the frame thereof, said hoppers having horizontal openings at their lower ends, a pair of doors for said hoppers, swinging links pivoted to said doors and to the car-frame, a connecting member secured to each of the pair of adjacent doors, an endless flexible member attached to said connecting member intermediate of the doors, and means for operating said flexible member.

11. A car provided with a pair of hoppers extending below the frame thereof, said hoppers having horizontal openings at their lower ends, a pair of doors for said hoppers, swinging links pivoted to said doors and to the car-frame, a connecting member secured to each of said pair of adjacent doors, an endless flexible member attached to said connecting member intermediate of the doors, an idler-pulley mounted above the pair of doors, a sprocket-wheel and winding-shaft for operating said flexible member to open and close the doors above.

12. In a dumping-car, a pair of doors mounted on outer and intermediate swinging links, a connecting member secured to each door of said pair, each door being composed of a flat body portion provided with side and end stiffening members attached thereto.

13. In a dumping-car, a pair of hoppers, one of which is located on each side of the center shaft and extends below the car-frame, said hoppers having horizontal openings at their lower ends, a pair of doors for said hoppers, swinging links pivoted to said doors and to the car-frame, a connecting member secured to each of said pair of doors, an endless flexible member attached to said connecting member intermediate of the doors, said flexible member being located in the open space between and below said car-shafts, and means for operating said flexible member to open and close the doors above.

14. In a dumping-car, two pairs of doors, a connecting member secured to the adjacent doors of each pair, an endless flexible member attached to each of said connecting members intermediate of the doors, and means for operating said flexible member, so that each of the two pairs of doors may be opened and closed independently of the other pair.

15. In a dumping-car, two pairs of doors mounted on swinging links, a connecting member secured to the adjacent doors of each pair, a separate continuous chain attached to each of said connecting members intermediate of the doors, and means for operating said chain so that each of the two pairs of doors may be opened and closed independently of the other pair.

16. In a dumping-car, two pairs of doors mounted on swinging links, a connecting member secured to the adjacent doors of each pair, a separate continuous chain attached to each of said connecting members intermediate of the doors, an idler-pulley mounted above each pair of doors,

a sprocket-wheel mounted on a winding-shaft supported by the car-framing and means for operating the same.

17. In a dumping-car provided with a pair of center sills, two pairs of doors mounted on swinging links, a connecting member secured to the adjacent doors of each pair, a separate continuous operating-chain for each pair of doors attached to said connecting member intermediate of the doors, an idler-pulley mounted above each pair of doors on a shaft supported by the center sills, a sprocket-wheel for each chain located between the center sills and mounted on a winding-shaft extending to the car side, and means for operating and locking said winding-shaft.

18. In a dumping-car provided with a pair of center sills, two pairs of doors mounted on swinging links, a connecting member secured to the adjacent doors of each pair, a separate continuous operating-chain for each pair of doors attached to said connecting member intermediate of the doors, an idler-pulley mounted above each pair of doors, a sprocket-wheel for each chain, said idler-pulleys and sprocket-wheels being mounted between said center sills, a winding-shaft for said sprocket-wheel extending to the side of the car, a ratchet-wheel mounted on said winding-shaft and a pawl and lock for co-operating with said ratchet-wheel.

19. In a dumping-car provided with a pair of center sills spaced apart, a pair of doors, a connecting member secured to each of said doors, swinging links pivoted to the outer ends of said doors and to the car-framing, and a middle swinging link pivoted to said connecting member intermediate of the doors, the upper pivot of said middle link being mounted between the center sills above said.

20. In a dumping-car provided with a pair of center sills, two pairs of doors mounted on swinging links, a connecting member secured to the adjacent doors of each pair, a separate continuous operating-chain for each pair of doors attached to said connecting member intermediate of the doors, an idler-pulley mounted above each pair of doors, a sprocket-wheel for each chain, said idler-pulleys and sprocket-wheels being mounted between said center sills, a winding-shaft for each sprocket-wheel extending from said center sills to the side of the car, a ratchet-wheel mounted on each winding-shaft, a pawl and lock mounted on the car side in co-operating with each ratchet-wheel, and a wrench or crank for operating each of the winding-shafts above said.

21. In a dumping-car provided with a pair of center sills spaced apart, a pair of doors, horizontal when in closed position; a connecting member secured to each of said doors, two swinging links pivoted to each of the outer ends of said doors and to the car-framing, a middle swinging link pivoted to said connecting member intermediate of the doors, the upper pivot of said middle link being mounted between the center sills above said; the swinging links nearest the transverse center line of the car being longer than those most distant from it whereby the doors when opened assume an inclined position.

22. In a dumping-car provided with a pair of center sills, two pairs of doors, a connecting member secured to the adjacent doors of each pair, a central supporting swinging link pivoted to each of said connecting members intermediate of the doors, the upper end of said middle swinging link being mounted on a shaft supported by the center sills above said, swinging links pivoted to the outer ends of said doors and to the car-framing, a separate continuous operating-chain attached to said connecting member intermediate of said doors, an idler-pulley mounted on a shaft supported by and between said center sills, a sprocket-wheel also mounted between said center sills on a winding-shaft extending to the car side, and means for operating and locking said winding-shaft.

23. In a dumping-car provided with oppositely-swinging doors mounted on vibratory links, a pair of locking-jaws pivoted to the car-framing between the inner edges of said doors, and means for operating said locking-jaws.

24. In a dumping-car provided with two pairs of oppositely-swinging doors, a stiffening and reinforcing member attached to the inner edges of each of said pairs of doors, a pair of locking-jaws pivoted between the pairs of doors, said locking-jaws being provided with inclined and vertical surfaces for automatically engaging with and securing said doors in closed position by co-operating with the stiffening and reinforcing members above said.

25. In a dumping-car provided with oppositely-swinging doors, a pair of locking-jaws mounted on a pin secured intermediate of said doors, said locking-jaws being provided with suitable surfaces for automatically engaging and locking the doors above said, and means for lifting and disengaging said locking-jaws.

26. In a dumping-car provided with a pair of oppositely-swinging doors, a pair of locking-jaws mounted on a pin secured intermediate of said doors, said locking-jaws being provided with suitable surfaces for automatically engaging with and securing said doors in closed position; link, crank and chain connections for lifting and disengaging said locking-jaws.

27. In a dumping-car provided with two pairs of oppositely-swinging doors mounted on vibratory links, a stiffening and reinforcing member attached to the inner edges of each pair of doors, a pair of locking-jaws

mounted between the pairs of oppositely-swinging doors, said locking-jaws being provided with suitable surfaces for engaging with the stiffening and reinforcing member above said, and means for lifting and disengaging said locking-jaws.

28. In a dumping-car provided with two pairs of oppositely-swinging doors mounted on vibratory links, a connecting member secured to the adjacent doors of each pair, a separate continuous operating-chain for each pair of doors attached to said connecting member intermediate of the doors, means for operating said chain, a stiffening and reinforcing member secured to the inner edges of said doors, a pair of locking-jaws mounted between said pairs of doors and provided with suitable surfaces for engaging with and securing said doors by means of the stiffening member above said, and means for lifting and disengaging said locking-jaws.

29. In a dumping-car, two pairs of oppositely-swinging doors mounted on vibratory links, a connecting member secured to the adjacent doors of each pair, a separate continuous operating-chain for each pair of doors attached to said connecting member intermediate of the doors, an idler-pulley mounted above each pair of doors, a sprocket-wheel for each chain, a winding-shaft for each sprocket-wheel extending to the side of the car, means for operating and locking said winding-shafts, a pair of locking-jaws pivoted intermediate of the pairs of doors and provided with suitable surfaces for engaging and securing said doors, and means for lifting and disengaging said locking-jaws.

30. In a bumper-car provided with a pair of center sills spaced apart, two pairs of oppositely-swinging doors mounted on vibratory links, a connecting member secured to the adjacent doors of each pair, a separate continuous operating-chain attached to each connecting member intermediate of the doors, an idler-pulley mounted above each pair of doors on a shaft supported by and between said center sills, a sprocket-wheel for each chain also mounted between said center sills on a winding-shaft extending to the car side, means for operating and locking said winding-shafts, a pair of locking-jaws pivoted intermediate of the pairs of doors and provided with suitable surfaces for automatically engaging and securing said doors, and means for lifting and disengaging said locking-jaws.

699,821. HAYE-THOMAS MACHINE. GEORGE S. THOMAS, Washington, D. C., assignor, by means of assignment, to the Federal Automatic Machine Company, New York, N. Y., a Corporation of New York. Filed June 1, 1901. Serial No. 68,716. (No model.)

Claim.—1. In a vending-machine, a magazine, an ejector carrying a rotator-bar, a latch-lever having a laterally-acting bearing-spring engaging a pivot, said latch-lever carrying a coin-cage, a coin-retainer spring extending through said cage and carried by the latch-lever, and a trip-arm carried by the ejector and engaging with said spring.

2. In a vending-machine, a magazine-chamber, a stationary guide-support, an ejector working on the said support, lock and release mechanism, co-operating with the ejector, and a guard-latch on the guide-support against which the package in the ejector lodges to prevent the return of the said ejector to a locked position before the operation of ejecting is completed.

3. In a vending-machine, a magazine, an ejector carrying a rotator-bar, a latch-lever having a laterally-acting bearing-spring engaging a pivot,

a coin-cage on the latch-lever, sliding slots in the walls of said cage, a coin-retainer arm projected through the said slots and carried by the latch-lever, and means on the ejector to engage said arm to release the coin from the cage.

4. In a vending-machine, a magazine, an ejector carrying a rotator-bar, a latch-lever having a laterally-acting bearing-spring engaging a pivot, said latch-lever carrying a coin-cage, a coin-retainer extending through said cage and carried by the latch-lever, and means on the ejector to engage said coin-retainer to free the coin from the coin-cage.

699,822. GUN-SILVER-FURNACE. ROBERT DODD, San Jose, Cal. Filed May 22, 1901. Serial No. 61,651. (No model.)

Claim.—1. A gun-silver-furnace provided with a series of fins over which the ore is adapted to pass, a fire formed in one or more of said fins and through which gases from said fire are adapted to pass, and means for directing said gases from said fire to said fins for the purpose set forth.

2. A gun-silver-furnace provided with a series of fins over which the ore is adapted to pass, one or more rods between said fins and provided with projecting ends, said rods being arranged for movement to engage said ore for the purpose set forth.

699,823. MECHANICAL MOVEMENT. JAMES W. SHARRARD and THOMAS W. LLOYD, Ashburn, Kans. Filed Feb. 26, 1901. Serial No. 61,928. (No model.)

Claim.—1. In a mechanical movement, a cam embodying three cam-faces of varying diameters arranged each with its highest point coincident with the neutral point of the next disk and with the points of merger at different circumferential points to the cam whereby a machine element co-operating with said cam travels from one to the other of the disks and changes from one to the other at periods less than a complete revolution of the cam.

2. A mechanical movement comprising a co-operating member suitably shaped, and a cam with which said member co-operates made up of three or more cam-faces concentric to the shaft, arranged so that the neutral point of one disk merges with the highest point of the next disk, and with said points of merger arranged in the same diametric line and alternately on opposite sides of the center of revolution, so that the co-operating member travels from one disk to another, and its periods of reversing or shifting when traveling from one extreme of the cam to the other, occur at half-revolutions of the cam.

3. A mechanical movement comprising a suitably-shaped lever arranged to perform work, a rotating shaft, a compound cam made up of a plurality of cam-faces concentric but eccentrically fixed to said shaft in different planes, and a ratchet-wheel carried by the lever, adapted to bear upon the cam, and having its periphery offset to operate in the planes of

the cam-faces the portions of the periphery of said ratchet-wheel which co-operate the respective disks.

4. In a mechanical movement the combination of the mounting 1, the lever 2 horizontally pivoted to said mounting, a ratchet-wheel 4 at the outer end of said lever, the plunger 6 connected to said lever 2, a constantly-rotating shaft 3 and a compound cam 5 composed of a plurality of concentric, eccentric cam-faces, in different planes, the periphery of the ratchet-wheel being offset to bring the portions of its rim into the planes of the cam-faces encountered thereby.

699,824. GRATE-BAR FOR FURNACE. HENRY SHERRILL, Chattanooga, Tenn. Filed Oct. 16, 1901. Serial No. 73,906. (No model.)

Claim.—1. The combination of hollow grate-bars provided with pivoted bottoms, a forced-draft air-pipe, conduits providing communication between the grate-bars and the forced-draft air-pipe, a damper in each of said conduits, said dampers being operatively connected with said pivoted bottoms, substantially as described.

2. A hollow grate-bar comprising closed side and end walls, an open-work top and a pivoted bottom, and a valve attached to said bottom and arranged at right angles thereto, said valve being adapted to control an air-draft opening leading into the grate-bar, substantially as described.

3. A furnace-grate comprising a plurality of hollow grate-bars each provided with a damping-bottom, a forced-draft air-pipe, conduits providing communication between the grate-bars and the forced-draft air-pipe, and a damper secured to and arranged at a right angle to each damping-bottom, said dampers controlling the passage of air through the conduits, substantially as described.

4. A hollow grate-bar having an air-tight opening and a damping-bottom, a valve for said air-tight opening, and means for discontinuously opening the bottom and closing the valve of the air-tight opening.

5. A hollow grate-bar having a damping-bottom and an air-tight opening, a valve for said air-tight opening, and means for discontinuously closing the bottom and opening the air-tight valve.

6. A hollow grate-bar having a damping-bottom and an air-tight opening, a valve for said air-tight opening, and means controlled by the position of said bottom for regulating the area of the air-tight opening.

7. A hollow grate-bar having a pivoted bottom and an air-tight opening, and a valve attached to said bottom and controlling said air-tight opening.

8. A furnace-grate comprising a plurality of hollow grate-bars, each of said bars being provided with a damping-bottom and an air-tight opening, a forced-draft air-pipe communicating with said air-tight openings, and a separate valve for each of said openings, said valves being attached to said bottoms.

9. A furnace-grate comprising a plurality of hollow grate-bars, each of said bars being provided with a damping-bottom and an air-tight opening, a forced-draft air-pipe communicating with said openings, and a separate valve for each of said openings operable from said bottoms.

10. A furnace-grate comprising a plurality of hollow grate-bars each having a pivoted bottom and an air-tight opening, means for forcing an artificial draft through said openings into the grate-bars, and valves for each of said openings attached to and operable from said pivoted bottoms.

699,825. PULVERIZING-MACHINE. MALCOLM A. SHIPLEY, Philadelphia, Pa. Filed Feb. 21, 1902. Serial No. 66,941. (No model.)

Claim.—1. In a taking-rod, a speed, gearing controlling the rotation of said speed, a shaft controlling said gearing, a friction-disk in lock-

ing engagement with said shaft, a second friction-disk loosely turning on the shaft, a handle connected to said friction-disk, a spiral spring bearing against the outer face of the second friction-disk to cause the same to contact with the first friction-disk, and means for adjusting the tension of said spring, substantially as and for the purposes described.

2. In a fishing-reel, a shaft controlling the movement of the spool of the reel, a disk locked to said shaft, a handle formed with a second friction-disk loosely turning upon the end of said shaft, a headed pin adapted to be advanced or retracted in the end of said shaft, and a spiral spring coiled around said pin, one end of said spring bearing against the head of the pin and the other end bearing upon the disk of the handle to force said disk into frictional contact with the disk locked to said shaft, substantially as and for the purposes described.

3. In a fishing-reel, a shaft controlling the movement of the spool of the reel, a disk locked to said shaft, a handle formed with a second friction-disk loosely turning upon the end of said shaft, a headed pin adapted to be advanced or retracted in the end of said shaft, a spiral spring coiled around said pin, one end of said spring bearing upon the head of the pin and the other end bearing upon the disk of the handle, and a cap insulating said spring and interposed between the head of the pin and the end of the shaft, substantially as and for the purposes described.

699,826. RIDGING-PLOW. JOSEPH C. SILVERA, San Francisco, Cal. Filed Jan. 20, 1902. Serial No. 99,467. (No model.)

Claim.—1. The combination in a ridging-plow, of an elongated handle, a vertically-disposed, endwise-adjustable plate or knife carried thereon, a plowshare, and an adjustable moldboard.

2. In a ridging-plow, the combination with the share and handle, of a pivoted moldboard, adapted to have a horizontal movement about its pivots, and means including a vertical bar and a projection adjustable thereon said projection fixed to said moldboard whereby the latter is also capable of a vertical adjustment in relation to the share.

3. The combination in a ridging-plow of an elongated handle, a plowshare, a moldboard pivoted thereto, a transverse beam adjustable in length supported between the handle and moldboard, connections including a vertical extension of one of the members of said beam and a projection on the moldboard said projection and extension adjustable one relative to the other, and means by which the moldboard may be adjustably supported at any desired angle above the ground.

4. The combination in a ridging-plow of an elongated handle, a plowshare, a moldboard pivoted rearward of said share, transverse braces connecting the share and handle, a beam adjustable in length between the moldboard and handle, a vertical projection on said beam and means in connection with said projection by which the moldboard may be engaged.

5. In a ridging-plow, a moldboard having outwardly-extending lateral flanges upon its upper and lower edges, in combination with a vertical projection of one of said flanges, and a member on which the projection is vertically adjustable.

6. In a ridging-plow, a moldboard substantially rectangular in form and having outwardly-extending flange projections upon its upper and lower edges, in combination with a vertical projection of the upper flange and a vertical extension above the moldboard to which the projection is adjustably secured.

7. A ridging-plow consisting in combination of an elongated handle, a vertically-disposed, endwise-slidable knife carried thereon, a share, a rectangular moldboard loosely pivoted at its upper and lower edges rearward of the share, means including a laterally-adjustable beam, a vertically-disposed bar and a projection of the moldboard adjustable on the bar by which said board may be moved vertically or horizontally about said pivots and securely held in any desired position, a pole pivoted intermediate of its ends, and means by which said pole may be held at any desired angle in relation to the handle, a coat upon and movable with said pole and a vertically-adjustable wheel-frame carried on the pole.

699,827. REPAIR-STRIP FOR BUTTONHOLE PORTIONS OF ARTICLES OF APPAREL. JOHN P. STOUT, Washington, D. C. Filed June 4, 1901. Serial No. 99,117. (No model.)

Claim.—1. As a new article of manufacture, a repair or renewal strip for the buttonhole portions of articles of apparel, the said strip containing a buttonhole and having a reinforced end and an adjacent thin portion, the said reinforced end being formed by a plurality of folds in the blank from which the strip is made.

2. As a new article of manufacture, a repair or renewal strip for the buttonhole portions of articles of apparel, the same containing a buttonhole and having a thin portion and a thick or reinforced portion adjacent thereto, the thin portion of said strip being provided with attaching means, and the thick or reinforced portion being formed by a plurality of folds in the blank from which the strip is made.

3. As a new article of manufacture, a repair or renewal strip for the buttonhole portions of articles of apparel, the same containing a buttonhole, having a reinforced end formed by a plurality of folds in the blank from which the strip is made, and having a flap extending beyond the reinforced portion.

4. As a new article of manufacture, a repair or renewal strip for the buttonhole portions of articles of apparel, the same containing a buttonhole, having a reinforced end formed by a plurality of folds in the blank from which the strip is made, and having a plurality of flaps extending beyond the reinforced portion.

5. As a new article of manufacture a repair or renewal strip for the buttonhole portions of articles of apparel, the same having a concave reinforced upper end containing a buttonhole, and a plurality of flaps extending below and beyond the opposite side ends of the reinforced portion.

6. As a new article of manufacture, a repair or renewal strip for the buttonhole portions of articles of apparel, the same having a concave reinforced upper end containing a buttonhole, and a flap extending below and beyond the opposite side ends of the reinforced portion.

7. As a new article of manufacture, a repair or renewal strip for the buttonhole portions of articles of apparel, the same having a concave reinforced upper end containing a buttonhole, and a flap extending below and beyond the opposite side ends of the reinforced portion, the said flap extending at an angle to the reinforced portion.

8. As a new article of manufacture, a repair or renewal strip for the buttonhole portions of articles of apparel, the same having a concave reinforced upper end formed by a plurality of folds in the blank from which said strip is made, cemented or otherwise secured together and containing a buttonhole, and flaps extending below the reinforced portion and beyond the opposite side ends thereof.

9. As a new article of manufacture, a repair or renewal strip for the buttonhole portions of articles of apparel, the said strip being made from a blank having incisions or indentations in the opposite side edges thereof and bent or folded and shaped to form a concave reinforced upper end, the folds being cemented or otherwise secured to each other, containing a buttonhole, and terminating short of the side and lower edges of the body of said strip.

699,828. ACETYLENE-GAS-GENERATING APPARATUS. ARTHUR E. ADOLFSSON, Stockholm, Sweden. Filed July 25, 1901. Serial No. 99,705. (No model.)

Claim.—In an acetylene-gas-generating apparatus, the combination with the generating-chamber and gasometer, of a carbide-feeding vessel, a feeding-plate therein, a shaft supporting the said plate, an arm or wheel on said shaft, a pin carried by said arm or wheel, a double lever secured to the shaft of the feeding vessel and having a curved outer back part on which said pin rests, pins carried by the branches of said double lever, a stationary guide on which one of the pins always moves when the lever

is moved by the pin on the arm or wheel, said guide, at parts corresponding to the extreme positions of the feeding vessel, having slots or edges extending radially inward permitting further movement of the wheel without turning of the feeding vessel, substantially as described.

699,899. PUMPING APPARATUS. JOHN ALABRUGH, San Francisco, Cal. Filed July 20, 1901. Serial No. 70,211. (No model.)

Claim.—1. The combination in a single apparatus of a horizontally-journalled water-wheel wholly or partly submerged within a stream and having buckets exposed to tidal conditions and the waves or current thereof whereby the wheel is operated by the natural power of the stream, pump-cylinders having plungers movable therein, means connected with the pump-cylinders and retaining a constant supply of water sufficient to supply the cylinders for one or more strokes, a windmill exposed to the air and operated by air-currents, a shaft and connections between the windmill and water-wheel, and connections between the water-wheel shaft and the pump-plungers.

2. In a pumping apparatus, wind and water wheels, with intermediate connections whereby the combined power of the two is transmitted, cranks or eccentrics mounted upon a supplemental shaft and mechanism by which power is transmitted from the driving-wheel thereto, fulcrumed levers having their upper ends connected with the eccentrics, and jointed links by which the intermediate portions of the levers are connected with the plunger-rods of the pump-cylinders, funnel into which the water is automatically delivered, connections between said funnel and the pump-cylinders whereby the latter are supplied, and the discharge-main, with which the pump-cylinders are connected.

699,880. CARBURETER. RABBIT, JR., San Leandro, Cal. Filed July 3, 1901. Serial No. 69,090. (No model.)

Claim.—1. A vaporizing apparatus consisting of an exterior casing, detaining-surfaces arranged therein from top to bottom, a plurality of passages extending through said surfaces connecting with a common chamber at the bottom and the top, a passage through which hot vapors are introduced into one of said chambers and passed thence through one of the pipes and returned through the other.

2. A vaporizing apparatus consisting of a casing having detaining-

surfaces arranged therein between top and bottom, chambers located above and below the apparatus and separated therefrom, a plurality of pipes extending through the surfaces and connecting said chambers, an inlet-passage through which hot products are introduced into one of said chambers and passed through the said pipes, and a gate movable in the chamber whereby the direction of movement of the heated products through the pipes is controlled.

3. A vaporizing apparatus consisting of a casing having detaining-surfaces arranged between the top and bottom, separate chambers located respectively above and below the apparatus, a plurality of pipes connecting said chambers, an inlet-passage by which hot exhaust products are delivered into one of said chambers, a gate by which said products are caused to pass through one of the pipes to the opposite end, and thence returned through the other pipe, and an exhaust-passage through which they are finally discharged, and means for changing the gate to alter the direction of movement of the hot products through the apparatus.

4. A vaporizer and generator consisting of an inclined casing having detaining-surfaces arranged therein between top and bottom, means for supplying oil to be vaporized upon one of the surfaces intermediate between the top and bottom, so as to form a superheater of the surfaces above, heating-pipes passing through the apparatus, and means for discharging the hot products of combustion from the engine through said pipes, an air-admission passage opening into the generator, and a gas-discharge passage located above the oil-admission passage.

5. A vaporizer and generator consisting of an exterior casing having detaining-surfaces arranged between the top and the bottom, pipes extending directly therethrough adapted to convey the hot exhaust products from the engine, a pipe for the admission of oil upon the surfaces near the top of the apparatus, a pipe for the admission of air near the bottom whereby the air is first brought into contact with the heavy products of vaporization, and a discharge-passage for the mixed products at the top of the apparatus.

6. In an apparatus for the production of explosive gas, a casing having detaining-surfaces arranged between the top and the bottom, pipes passing through said surfaces and adapted to conduct the hot products of combustion from the engine whereby the oil is vaporized, an air-inlet passage opening into the lower part of the generator, and a discharge-passage from the upper part whereby the air is first brought into contact with the gases evolved from the heavy oil near the bottom and successively with the lighter gases above before being discharged.

7. The combination in an apparatus for the production of explosive gas of a vertically-disposed closed chamber, a series of surfaces interposed between the top and bottom, with means discharging successively from the upper to the adjacent lower one, means for heating said surfaces, consisting of pipes passing therethrough, retarding-ribs and indentations formed upon the surfaces, and passages through which a hydrocarbon liquid is delivered upon the surfaces near the top.

8. The combination in an apparatus for the production of explosive gas of a normally vertical closed casing, a series of surfaces disposed between the top and bottom with serpentine discharges from the upper to the lower ones, heat-pipes passing through said surfaces, means for supplying a hydrocarbon liquid upon one of the upper surfaces, and detaining ribs and pockets upon said surfaces to prevent too rapid flow when the apparatus is tilted from a vertical position.

9. The combination in a vaporizing apparatus of a normally vertical closed casing, surfaces disposed therein between the top and bottom, said surfaces fitting against the interior of the casing and having a series of serpentine connecting-passages, a hydrocarbon-inlet near the top, an air-inlet at the bottom and a gas-discharge at the top, and heating-pipes passing vertically through the surfaces interior to the casing.

10. The combination in an apparatus for the production of explosive gas, of a closed vertically-disposed chamber with a series of transverse surfaces between the top and bottom, having serpentine connections, a hydrocarbon-supply to a surface near the top, an air-inlet at the bottom, and a gas-discharge at the top, independent chambers exterior to the top and bottom of the main chamber and heat-conducting pipes connecting said chambers and passing through the interior of the main chamber and through each of the surfaces.

699,881. LOCK. CHARLES E. BROWN, Yonkers, N. Y. Filed June 17, 1900. Serial No. 750,890. (No model.)

Claim.—1. A lock comprising a plate having holes adapted to receive screws or other attaching devices, a hump linged thereto and

meant to close over said plate and carrying a spring-actuated bolt, key-operated means for actuating said bolt, tumbler mechanism for normally preventing the retraction of the bolt except by a key, and means accessible solely when the key is opened for displacing the tumbler mechanism to permit the bolt to be retracted without the use of a key.

2. A lock comprising a latching-bolt, a bolt-retracting plate, a slot in one of said members elongated longitudinally of the bolt, and a pin on the other member occupying said slot, a spring engaged primarily with the bolt and normally projecting said bolt and the plate, a key-operated member adapted to engage and retract the plate, and thereby retract the bolt, a knob projecting from the bolt-retracting plate, and one or more key-operated tumblers normally obstructing the plate and preventing its retraction.

3. A lock comprising a casing, a bolt mounted therein, key-actuated means for operating said bolt, a series of bolt-controlling tumblers normally spring-held in bolt-obstructing positions and movable in opposite directions into bolt-releasing positions, a casing including said parts, and a rotary member mounted in the casing and exposed externally through a hole therein, said member having tumbler-displacing elements interposed between the tumblers and adapted when the member is rotated, to move the tumblers into bolt-releasing positions.

4. A lock comprising a plate, a key-bolted thereto and provided with a lock-casing, a bolt mounted in said casing, a series of key-operated bolt-controlling tumblers within the casing, a bolt-retracting knob located on the outer side of the casing and a tumbler-displacing device located on the inner side of the casing.

699,883. COMBINED WIRE-CUTTER AND PLIERS. FREDERICK B. BROWN, JR., N. Y. Filed Mar. 20, 1901. Serial No. 69,981. (No model.)

Claim.—1. In combination, two levers pivoted together, jaws formed with or secured to said levers, two side plates secured one to each of the jaws upon one side thereof, the heel ends of said side plates being pivoted together upon the outside of the main joint of the pliers, cutting edges formed upon each of said side plates, a plate secured to one of the jaws upon the opposite side thereof, the heel end of said plate being pivoted upon the same pivot as the jaws, substantially as described and for the purpose specified.

2. In combination, a pair of handle-levers led together and pivoted to each other, a pair of jaws formed with or secured to said levers, two removable plates, one secured to each of the said jaws upon one side thereof, the heel ends of said plates being pivoted together upon one side of the pivotal point of the jaws, cutting edges formed upon said plates at the point where said plates meet when the pliers are closed, a stop formed upon each member of the pliers, said stops adapted to engage one another when the jaws are open to a certain point for the purpose of limiting the movement of the same, substantially as described and for the purpose specified.

3. In combination, a pair of handle-levers led together and pivoted to each other, concentric portions formed concentric with the pivotal point formed with each of said levers, cavities formed upon the inside of each of the jaws and also the upright part of the concentric portions, a point comparatively near the pivot, stops formed upon one edge of each of said concentric portions and adapted to engage one another when the jaws of the pliers are open to a certain point, diagonal slots formed in the opposite edge of the concentric portions for the purpose of cutting or shearing wire, said diagonal slots adapted to register with one another when the shearing stops upon the opposite edges are in contact with one another, jaws formed with or secured to the handle-levers, two side plates, one secured to each of said jaws, the heel ends of said side plates being pivoted together, cutting edges formed upon said side plates, a plate upon the opposite side of the pliers, said plate being pivoted to one of the jaws, the heel end of said plate being pivoted upon the same pivot as the handle-levers and jaws, substantially as described and for the purpose specified.

699,888. LEATHER-GRIPPING DEVICE. JOHN CALDWELL, Minneapolis, Minn., assignor to the W. S. Eddy Company, Minneapolis, Minn., a Corporation. Original application filed Jan. 26, 1900, Serial No. 1,494. Divided and this application filed Jan. 2, 1901. Serial No. 69,988. (No model.)

Claim.—1. In a leather-gripping machine, the combination with a stretcher-head, of a series of independent leather-holders adjustable lat-

erally and longitudinally thereof, and a corresponding series of coupling devices having laterally-adjustable pivotal connection with the holders adapting the latter to swing freely under tension, and means for independently pivoting each of said coupling devices to the stretcher-head, substantially as set forth.

2. In a leather-gripping machine, the combination with a stretcher-head, of a series of leather-holders adapted to engage marginal portions of leather at different inclinations to the direction of tension upon it, coupling devices having two pivotal connection with the holders for effecting them to a member of the stretching mechanism, means for lateral variation of the points of each pivotal connection corresponding with the varying inclinations of the holders, and means for adjustably and pivotally connecting such coupling devices to the stretcher-head, substantially as set forth.

3. In a leather-gripping machine, the combination with a stretcher-head, of a series of leather-holders adapted to engage marginal portions of leather at different inclinations to the direction of tension upon it, coupling devices having two pivotal connection with the holders for effecting them to a member of the stretching mechanism, means for lateral variation of the points of each pivotal connection corresponding with the varying inclinations of the holders, and means for independently and successively pivotally connecting such coupling devices to the stretching mechanism, substantially as set forth.

4. The combination with a leather-holder and a stretcher-head, of a coupling-bar having a laterally-adjustable pivotal connection with the holder adapted to permit the holder to swing freely under tension, and means for adjustably and pivotally connecting such bar to said head, substantially as set forth.

5. The combination with a stretcher-head, of a leather-holder having means for the laterally-adjustable pivotal connection of a coupling device adapted to permit the holder to swing freely under tension, a coupling-bar, and means for adjustably and pivotally connecting such bar to the leather-holder and to the stretcher-head, substantially as set forth.

6. A leather-holder for a stretching machine, consisting of a body provided with means for engaging the leather and having in rear of the leather-engaging member a slot concave in the direction of the latter, a coupling-bar adapted to engage in said slot and thereby pivotally connect said body to said bar, and means for adjustably and pivotally connecting the coupling-bar to the stretching mechanism.

699,884. TOY BLOCK. EDWARD A. GARDNER, Greenwich, Wt. Filed Feb. 2, 1901. Serial No. 69,979. (No model.)

Claim.—1. The combination of longitudinal side connecting-blocks having longitudinal grooves on their under sides, a bottom block or blocks fitted to said longitudinal connecting-blocks, bearing-blocks fitted in the longitudinal grooves on the under side of the side connecting-blocks, said bearing-blocks provided with openings therethrough, axle-blocks having reduced ends fitting in the openings of the bearing-blocks, and wheel blocks mounted on the reduced ends of the axle-blocks between the shoulders of said axle-blocks and the inner sides of the side connecting-blocks.

2. The combination of side connecting-blocks provided with longitudinal grooves upon their inner sides, and with longitudinal grooves upon their under sides, and connecting-blocks provided with longitudinal grooves upon their inner sides, a bottom block or blocks having in or their side edges fitting in the side grooves of the side connecting-blocks, bearing-blocks fitted in the longitudinal grooves on the under sides of the side connecting-blocks, said bearing-blocks provided with openings therethrough, axle-blocks having reduced ends fitting in the openings of the bearing-blocks, and wheel blocks mounted on the reduced ends of the axle-blocks between the shoulders of said axle-blocks and the inner sides of the side connecting-blocks.

3. The combination of side connecting-blocks provided with longitudinal grooves on their inner sides, a central longitudinal block provided with longitudinal grooves on its opposite side edges, and bottom blocks having their outer edges fitting in the grooves on the inner sides of the side connecting-blocks, and having their inner edges fitting in the grooves on the opposite side edges of the central longitudinal block.

4. The combination of side connecting-blocks provided with longitudinal grooves on their inner sides, a central longitudinal block provided with longitudinal grooves on its opposite side edges, two connecting and blocks at each end, and between the inner ends of each end thereof the ends of the central longitudinal block fit, said end connecting-blocks provided upon their inner sides with grooves, and bottom blocks having their outer side edges fitting in the grooves of the side connecting-blocks, and their inner side edges fitting in the side grooves of the central longitudinal block, and their end edges fitting in the inner grooves of the end connecting-blocks.

5. The combination of side connecting-blocks provided with longitudinal grooves on their inner sides, a central longitudinal block provided with longitudinal grooves on its opposite side edges, two end connecting-blocks at each end, and between the inner ends of each end thereof the ends of the central longitudinal block fit, and project outwardly therefrom to form projecting draw-bars, said end connecting-blocks provided upon their inner sides with grooves, and bottom blocks having their outer side edges fitting in the grooves of the side connecting-blocks, and their inner side edges fitting in the side grooves of the central longitudinal block, and their end edges fitting in the inner grooves of the end connecting-blocks.

6. The combination of side connecting-blocks provided with longitudinal grooves on their inner sides, a central longitudinal block provided with longitudinal grooves on its opposite side edges, two end connecting-blocks at each end, and between the inner ends of each end thereof the ends of the central longitudinal block fit and project outwardly therefrom to form projecting draw-bars, said end connecting-blocks provided upon their inner sides with grooves, and bottom blocks having their outer side edges fitting in the grooves of the side connecting-blocks, and their inner side edges fitting in the side grooves of the central longitudinal block, and their end edges fitting in the inner grooves of the end connecting-blocks.

7. The combination of lower side connecting-blocks having longitudinal grooves in their upper sides, and also upon their inner sides, lower end connecting-blocks having longitudinal grooves in their upper sides and also in their inner sides, a bottom block or blocks having in or their outer side edges fitting in the inner side grooves of the lower end connecting-blocks, and their end edges fitting in the inner grooves of the lower end connecting-blocks, upper longitudinal side connecting-blocks having longitudinal grooves upon their under sides, and side and end blocks having longitudinal grooves upon their under sides, and side and end blocks fitting in the upper grooves of the lower side and end connecting-blocks, and their upper ends fitting in the under grooves of the upper longitudinal side and end connecting-blocks.

8. The combination of lower side connecting-blocks provided with longitudinal grooves on their inner sides and also upon their upper sides, a central longitudinal block provided with longitudinal grooves on its opposite side edges and also with cross-grooves on its upper side near opposite ends thereof, two lower connecting-blocks at each end, and between the inner ends of each end thereof the ends of the central longitudinal block fit, and said lower end connecting-blocks provided upon their inner sides with grooves and also upon their upper sides with grooves, bottom blocks having their outer edges fitting in the grooves on the inner sides of the lower side connecting-blocks, and their inner edges fitting in the side grooves of the central longitudinal block, and their end edges fitting in the inner grooves of the lower connecting and blocks, upper longitudinal side connecting-blocks having grooves on their under sides, and side and end blocks having side and end pieces and having, respectively, their lower ends fitting in the upper grooves of the lower side connecting-blocks, and in the upper grooves of the central longitudinal block, and their upper ends fitting in the under side grooves of the upper longitudinal side and end connecting-blocks.

9. The combination of a structure having side pieces, at opposite sides and ends, upper longitudinal side connecting-blocks to which said side pieces are connected, said side connecting-blocks provided upon their inner sides with longitudinal grooves, upper end connecting-blocks to which the end pieces of the structure are connected, said end connecting-blocks provided upon their inner sides with grooves, two flat blocks at opposite ends, the outer edges of each of these blocks fitting in the side grooves of the upper longitudinal side connecting-blocks, and their end edges fitting in the grooves of the upper end connecting-blocks, the inner edges of said flat blocks being out of contact with each other, coupling-

blocks provided with grooves in opposite sides in which grooves the inner edges of the flat blocks fit, said coupling-blocks provided upon their upper sides with longitudinal grooves, upright blocks fitting in the upper grooves of these coupling-blocks, and a roof having the ridge block or piece thereof provided upon its under side with a longitudinal groove which receives the upper edges of the upright blocks.

10. The combination with a structure having upright blocks extending upwardly from opposite ends thereof, a longitudinal ridge-block provided upon its under side with a longitudinal groove which receives the upper edges of the upright blocks, and said ridge-block provided upon opposite sides with downwardly-facing grooves, and roof-blocks having their inner edges fitting in the channel grooves of the ridge-block.

11. The combination of lower longitudinal side connecting-blocks having grooves upon their upper sides, lower end connecting-blocks having grooves upon their upper sides, a bottom piece connected to the lower side and end connecting-blocks, upright corner-blocks each having grooves in its two inner faces, upper longitudinal side connecting-blocks having grooves upon their under sides, upper end connecting-blocks having grooves upon their under sides, side blocks forming side pieces and having their lower ends fitting in the upper grooves of the longitudinal lower side connecting-blocks, and their upper ends fitting in the under grooves of the upper longitudinal side connecting-blocks, and their end edges fitting in one of the grooves of the upright corner-blocks, and two end blocks for forming each end of the structure, the lower ends of said end blocks fitting in the upper grooves of the lower end connecting-blocks, and the upper ends thereof fitting in the under grooves of the upper end connecting-blocks, and the outer side edges of said end blocks being out of contact with each other, the longitudinal projecting edge of each between said end-ways portion fitting in one of the grooves of the upright corner-blocks.

12. The combination of lower longitudinal connecting side blocks having grooves upon their upper sides, lower end connecting-blocks having grooves upon their upper sides, a bottom piece connected to the lower side and end connecting-blocks, upper longitudinal side connecting-blocks having grooves upon their under sides, upper end connecting-blocks having grooves upon their under sides, side blocks forming side pieces and having their lower ends fitting in the upper grooves of the lower side connecting-blocks, and their upper ends fitting in the under grooves of the upper side connecting-blocks, and two end blocks forming the end pieces at each end, the lower ends of said end blocks fitting in the upper grooves of the lower end connecting-blocks, and the upper ends thereof fitting in the under grooves of the upper end connecting-blocks, the inner edges of said end blocks or pieces, at medial points, provided with recesses which, when the end pieces are adjusted, register and form a window.

13. The combination of upper and lower side connecting-blocks and upper and lower end connecting-blocks, blocks forming side pieces and having their opposite ends connected to said upper and lower side and end connecting-blocks, a space being left between the inner edges of the innermost side blocks or pieces to form a doorway, blocks forming the side joints of the doorway, said blocks provided upon their outer sides with grooves to receive the inner edges of the side blocks or pieces.

14. The combination of upper and lower side connecting-blocks and upper and lower end connecting-blocks, blocks having their opposite ends connected to said upper and lower side and end connecting-blocks and forming side pieces, a space being left between the inner edges of the innermost side blocks or pieces to form a doorway, blocks forming the side joints of the doorway, said blocks provided upon their inner edges with grooves and upon their outer edges with grooves the latter grooves to receive the inner edges of the side blocks or pieces, and a door-block having its opposite side edges fitting in the inner grooves of the side joints.

15. The combination of longitudinal side connecting-blocks having grooves upon their upper sides, connecting and blocks having grooves upon their upper sides, side blocks forming side pieces and having their lower edges fitting in the upper grooves of the longitudinal side connecting-blocks, and end blocks forming end pieces having their lower edges fitting in the upper grooves of the end connecting-blocks.

16. The combination of longitudinal side connecting-blocks having grooves upon their upper sides, and connecting-blocks having grooves upon their upper sides, upright corner-blocks each having longitudinal grooves in two of its faces, side blocks forming side pieces, the lower edges of said side pieces fitting in the grooves in the upper sides of the side connecting-blocks, and their end edges fitting in one of the grooves of the corner-block, and end blocks forming end pieces, said end blocks or pieces having their lower edges fitting in the grooves of the upper side of the end connecting-blocks, and their end edges fitting in the other side grooves of the corner-blocks.

17. The combination of side connecting-blocks having grooves in their inner sides and grooves upon their under sides, a bottom block or blocks having in or their outer edges fitting in the inner grooves of the side connecting-blocks, bearing-blocks fitted in the grooves on the under sides of the side connecting-blocks, an axle-block having its ends mounted

In openings in the bearing-blocks, wheel-blocks mounted on the axle-block, log-blocks at the rear and on the outer side of the side connecting-blocks, mid log-blocks having longitudinal grooves upon opposite sides, and brace-blocks each having one edge fitting in one of the side grooves of the log-block, and another edge fitting in the under groove of the side connecting-block.

18. The combination of side connecting-blocks having grooves in their inner sides, a bottom block or blocks having its or their outer edges fitting in the inner grooves of the side connecting-blocks, handle-bar blocks fitting in the inner grooves of the side connecting-blocks, and a handle-block connecting the ends of the handle-bar blocks.

19. The combination of side connecting-blocks having grooves in their inner sides, a rear end block having a groove upon its inner side, and provided at opposite ends with grooves, a bottom block or blocks having its or their outer side edges fitting in the inner grooves of the side connecting-blocks and the rear edge fitting in the inner groove of the rear end block, handle-bar blocks fitting in the inner grooves of the side connecting-blocks and the ends of the handle-bar blocks, and a handle-block connected to the ends of the handle-bar blocks.

20. The combination of side connecting-blocks having grooves in their inner sides and also upon their upper sides, a bottom block or blocks having its or their outer edges fitting in the inner grooves of the side connecting-blocks, blocks projecting upwardly from the upper sides of the forward ends of the side connecting-blocks and at a forward incline, said inclined blocks provided upon their inner sides with grooves and upon their forward sides with grooves, side-blocks connecting the inner grooves of the inclined blocks, and brace-blocks fitted to the forward grooves of the inclined blocks and to the upper grooves of the side connecting-blocks.

21. The combination of a base-block provided with an opening therein, a spindle or axle block having its lower end revolvably fitting in said opening, longitudinal side connecting-blocks, a bottom block or blocks connected to the side connecting-blocks, and said bottom block or blocks being revolvably mounted on the upper end of the spindle-block.

22. The combination of a base-block provided with an opening therein, a spindle or axle block having its lower end revolvably fitting in said opening, longitudinal side connecting-blocks having grooves on their inner sides, a bottom block or blocks having its or their outer edges fitting in the inner grooves of the side connecting-blocks, and said bottom block or blocks being revolvably mounted on the upper end of the spindle-block.

23. The combination of a base-block provided with an opening therein, blocks provided upon their inner sides with grooves which the side edges of the base-block fit, a spindle or axle block having its lower end revolvably fitting in the opening of the base-block, longitudinal side connecting-blocks, a bottom block or blocks connected to the side connecting-blocks, and said bottom block or blocks being revolvably mounted upon the upper end of the spindle-block.

24. The combination of a base-block provided with an opening therein, side bordering-blocks provided upon their inner sides with grooves which the side edges of the base-block fit, and upon their upper sides with grooves, side-blocks fitting in the upper grooves of the border-blocks, a wheel-block seated on the base-block between the side-blocks, the opening of said wheel-block registering with the opening of the base-block, a spindle or axle block having its lower end reduced, said reduced end revolvably engaging the registering openings of the wheel-block and the base-block, longitudinal side connecting-blocks, and a bottom block or blocks connected to the side connecting-blocks, and said bottom block or blocks being revolvably mounted on the upper end of the spindle-block.

25. The combination of a base-block provided with an opening therein, side bordering-blocks provided upon their inner sides with grooves which the side edges of the base-block engage, and border-blocks provided upon their inner sides with grooves which the end edges of the base-block engage, a spindle or axle block having its lower end revolvably fitting in the opening of the base-block, longitudinal side connecting-blocks, and a bottom block or blocks connected to the side connecting-blocks, and said bottom block or blocks being revolvably mounted upon the upper end of the spindle-block.

26. The combination of a base-block provided with an opening therein, a spindle or axle block having its lower end revolvably mounted in the opening of the base-block, the upper end of said spindle-block being reduced, a wheel-block mounted on said reduced end, longitudinal side connecting-blocks, and a bottom block or blocks connected to the longitudinal side connecting-blocks and resting upon the wheel-block, the said bottom block or blocks being revolvably mounted upon the upper end of the spindle-block.

27. The combination of longitudinal side connecting-blocks having grooves upon their upper sides, a bottom block or blocks connected to the side connecting-blocks, the blocks fitted in the upper grooves of the side connecting-blocks at the ends thereof, blocks (see 79) having grooves upon their outer sides which the side-blocks engage, and also provided with grooves upon their inner sides and upon their upper sides, side-blocks

having their opposite ends engaging said inner grooves and forming the bottom of a seat, upright blocks extending upwardly from the ends of the blocks 79, said upright blocks having grooves upon two of their faces, side-blocks connecting the opposite grooves on the inner faces of said upright blocks, and forming the back of the seat, and brace-blocks engaging the other grooves of the upright blocks and also engaging the grooves in the upper sides of the blocks 79 and brace-blocks forming the side arms of the seat.

28. The combination of a base-block, a spindle revolvably mounted in said base-block, longitudinal side connecting-blocks, bottom blocks connected to the longitudinal side connecting-blocks, the inner edges of said bottom blocks being cut off and thereby forming a space in the bottom, in which space the spindle extends, blocks seated upon the bottom blocks and between the inner sides of the longitudinal side connecting-blocks, said blocks provided upon their inner faces with longitudinal grooves, and cross-blocks having their opposite ends extending into said grooves, the space between the cross-blocks receiving the upper extremity of the spindle-block revolvably therein.

699,885. INDOTRAP. BRASS CURTAINS, Manchester, England. Filed Mar. 18, 1901. Serial No. 61,898. (No model.)

Claim.—1. In an iron bedstead, the combination with the independent side and end members, of corner-brackets for securing said members together, said corner-brackets having sockets, and vertical rods supported by said brackets, substantially as described.

2. In an iron bedstead, the combination with the independent side and end members, of corner-brackets for securing said members together, said corner-brackets having sockets, vertical rods supported in said sockets, horizontal rods at the top of the inclined rods forming a rectangular frame, inclined rods from corners of the frame to lower ends of the vertical rods, detachable connections between some of the adjoining ends of the vertical and horizontal and inclined rods, and hinge connections between the remaining of the adjoining ends of said rods, substantially as described.

3. In an iron bedstead, the combination with the side and end members, of sockets at the corners thereof, vertical rods supported by said sockets, horizontal side and end rods having a sliding connection with the upper ends of two of said vertical rods and a detachable connection with the other two, and inclined rods having sliding connections to the upper ends of said other two rods, substantially as described.

699,886. HORNHOLE-GALE. JOHN E. CROSBYMAN, St. Albans, Vt. Filed Feb. 21, 1902. Serial No. 55,126. (No model.)

Claim.—1. A shoe-calk provided with lugs for engaging the outer wall of the toe portion of the shoe, and with a rearward-extending plate having an orifice therein, a bolt having a groove to engage the rear wall of the orifice and provided with a shoulder to engage the inner wall of the toe portion of the shoe, and a locking-key engaging the bolt and the bolt, substantially as described.

2. A shoe-calk provided with curved lugs for engaging the outer wall of the toe portion of the shoe and with a rearward upward extending plate having an orifice therein, a bolt having a groove to engage the rear wall of the orifice and provided with a shoulder to engage the inner wall of the toe portion of the shoe, and a transversely-disposed, wedge-shaped locking-key adapted to engage with the bolt and the bolt and to have one end downturned to lock it against accidental operation, substantially as described.

3. A shoe-calk provided with a pair of curved lugs to engage with the toe portion of the shoe and with a rearward upward extending plate having an orifice therein, the rear wall of which is disposed in alignment with the outer side of the shoe, a bolt having a groove to engage the

and rear wall, and an angular shoulder to engage with the shoe, and a transversely-disposed locking-rod adapted to engage with the bolt and the bolt, respectively in the bolt and in the shoe, substantially as described.

699,887. DOOR-CALIBRATOR. GEORGE W. BROWNE, Chicago, Ill. Filed Dec. 30, 1901. Serial No. 57,851. (No model.)

Claim.—1. In a door-calibrator, the combination of the frame, the removable sign-plate, the dial-rod attached below said plate and projecting forward of the plate thereof, the apertured plate covering said dial and the edges of said case, the hand covering said plate to said case, the pointer, the pointer-hub in range of the aperture in said plate, the zero or neutral mark fixed perpendicularly above said hub, the sign-plate projecting from the frame below and beyond said dial, the shaft-stands mounted in said case, the spring-stop attached to the lower side of one of said stands, the cylinder-shaft in said stands, the cylinder-heads secured to said shaft, the number plate having the numbers therein and secured to the outer side of one of said heads in contact with said stop, the card-holders attached to said heads, the cards in said holders, and the data secured to said frame and extending from the rear under side of said sign-plate, substantially as shown and described.

2. In a door-calibrator, the combination of the frame, the pair of removable sign-plates extending across the upper end of said frame, the dial-rod projecting from said frame immediately below said plates, the zero-mark fixed below the center of the lower end of said plates, the pointer, the apertured glass plate, the retaining-band, the sign-plate attached to said frame adjacent to said dial-rod, the glass plate at the front of said sign-plate, the counterbalance at the end of said sign-plate, the cylinder-shaft mounted in said sign-plate, the spring-stop secured to the lower side of one of said stands, the shaft mounted in said stands with the upper end thereof adjacent to said counterbalance, the cylinder-heads secured to said shaft, one of which is adjacent to said stop, the number plate having the numbers therein attached to the outer side of said head but described and in contact with said stop, the card-holders extending from one of said heads to the other one and secured therein, each of said holders being formed of strips having their edges turned over toward each other, the cards in said holders, and the data extending from the rear under side of said sign-plate downwardly and protected thereby from the rain, substantially as shown.

699,888. SAND-BLASTING APPARATUS. MYRON E. SWAN, New York, N.Y. Filed Dec. 6, 1900. Serial No. 730,008. (No model.)

Claim.—1. In a sand-blast apparatus a nozzle-body, consisting of an air-chamber, an inner nozzle, and a detachable outer nozzle, the adjacent surfaces of said air-chamber and said inner nozzle forming an annular opening when said outer nozzle is detached, and the adjacent surfaces of said inner and outer nozzle forming an annular opening when said outer nozzle is attached.

2. The combination in a sand-blast apparatus of a reservoir, a mixing device, means for delivering sand from the said reservoir to the said mixing device, a nozzle-body consisting of an inner nozzle and an air-chamber and having an annular opening formed by the adjacent surfaces of the said inner nozzle and the said air-chamber, means for conveying sand from the said mixing device to the said inner nozzle, an air-driving apparatus, means for connecting the said air-driving apparatus and the said air-chamber.

3. In a sand-blast apparatus a nozzle-body consisting of an air-chamber and an inner nozzle, the adjacent surfaces of the said inner nozzle and the said air-chamber forming an adjustable annular opening.

4. In a sand-blast apparatus a nozzle-body consisting of an air-chamber, an inner nozzle, and a detachable outer nozzle, the adjacent surfaces of said air-chamber and said inner nozzle forming an adjustable annular opening when said outer nozzle is detached, and the adjacent surfaces of said inner and outer nozzle forming an adjustable annular opening when said outer nozzle is attached.

5. In a sand-blast apparatus a nozzle-body, consisting of an air-chamber, an inner nozzle, and a detachable discharging-nozzle, the adjacent surfaces of the said inner nozzle and the said discharging-nozzle forming an annular opening.

6. The combination in a sand-blast apparatus of a discharging-nozzle, an air-driving apparatus, means for connecting the said air-driving apparatus and the said discharging-nozzle, an inner nozzle projecting into the said discharging-nozzle, a mixing device, and an adjustable reducer situated between the said inner nozzle and the said discharging-nozzle.

7. The combination in a sand-blast apparatus of a mixing device, a nozzle, means for connecting the said mixing device and the said nozzle, means for conveying a blast of air past the end of said nozzle and inducing a current of air through the said nozzle and the said mixing device.

8. In a sand-blast apparatus a nozzle-body consisting of an air-chamber and an inner nozzle, the adjacent surfaces of the said inner nozzle and the said air-chamber forming an annular opening, and means for regulating the area of said annular opening.

9. In a sand-blast apparatus a nozzle-body consisting of an air-chamber and an inner nozzle adapted to be moved backward and forward and held in various positions, the outer surface of said nozzle-body being conical-shaped, and forming with the adjacent inner surface of said air-chamber an annular opening whose area varies according to the relative position in which said inner nozzle is held.

10. The combination in a sand-blast apparatus of a mixing-box having pipes entering said box at opposite sides, but in substantially the same vertical and horizontal planes, but leaving a space between the interior adjacent extremities of said pipes; a nozzle; means for connecting said nozzle to one of said pipes; and means for discharging a blast of air past the end of said nozzle and inducing a current of air through the said nozzle and the said pipes.

11. The combination in a sand-blast apparatus of a nozzle-body, consisting of a nozzle and an air-chamber, and having an annular opening formed by the adjacent surfaces of said nozzle and air-chamber; an air-driving apparatus; means for connecting said air-driving apparatus and said air-chamber; a mixing-box having pipes entering said box at opposite sides, but in substantially the same vertical and horizontal planes, and leaving a space between the interior adjacent extremities of said pipes; and means for connecting said nozzle to one of said pipes.

12. In a sand-blast apparatus a mixing device, consisting of a mixing-box having an opening for the admission of sand, and two conduits entering said box at opposite sides, but in substantially the same horizontal and vertical planes, and adapted to have an adjustable space between their inner adjacent extremities.

13. In a sand-blast apparatus the combination of a nozzle and mixing device, means for connecting said nozzle and said mixing device, means for conveying a blast of air past the end of said nozzle and inducing a current of air through said nozzle and said mixing device, and a reservoir adapted to supply said mixing device with sand, and also to be coupled as will without stopping the operation of the apparatus.

699,889. DRY-KILN. EDWARD GERRARD, Indianapolis, Ind., assignor to the National Dry Kiln Company, Indianapolis, Ind., a Corporation of Indiana. Filed Apr. 3, 1901. Serial No. 84,111. (No model.)

Claim.—1. A dry-kiln having a suitable floor, walls and roof, with doors at the ends said floor having suitable openings near one end for the admission of air, and escape-flues at the other end having widened lower ends, one side of said flues being inclined, and the exposed side extending at right angles therewith being provided with a series of closable ingress-openings arranged parallel to the inclined edge, substantially as set forth.

2. The combination, with a dry-kiln, of escape-flues therefor located at one end thereof, said flues having inclined rear edges and a series of adjustable closable ingress-openings near to and at equal distances from said inclined rear edges, substantially as and for the purpose set forth.

3. The combination, in a dry-kiln, of the body thereof, flues therein having widened lower ends provided with ingress-openings equidistant from the inclined side thereof, doors to said openings, and handles to said doors extending to a convenient point for the operator, substantially as shown and described.

699,840. WIRELESS PLANO. E. F. GILBERT, Birmingham, Ala. Filed June 28, 1901. Serial No. 66,968. (No model.)

Claim.—1. In a wireless piano, the combination with a casing, of a laterally-movable sound-box therein, said box having a sounding-board constituting the rear wall thereof, of reeds having their rear ends located contiguous to the sounding-board and extended beyond the front of the box, a sound-chamber movable with the box, means for operating the reeds, and means extended beyond the casing for moving the box.

2. In a musical instrument, the combination with a sound-box having a sounding-board constituting the rear wall thereof, of a series of reeds having their rear ends located contiguous to the sounding-board, a sound-chamber partially inclosing the reeds and having an open side located within the sound-box, and reed-operating mechanism disposed to engage the front ends of the reeds.

3. In a wireless piano, the combination with a casing and a vertically-disposed and tiltable-mounted sound-box therein having a sounding-board constituting the rear wall of the box, of a series of reeds within the box and extended beyond the front wall thereof, reed-operating mechanism located in advance of the reeds, and means extended beyond the casing for tilting the sound-box to effect the endwise adjustment of the reeds.

4. In a musical instrument, the combination with a sound-box having a sounding-board constituting its rear wall, of a semicylindrical sound-chamber extended from the front wall of the sound-box and having an open side disposed adjacent to the sounding-board, a series of reeds partially inclosed by the sound-chamber, reed-operating mechanism disposed to engage the front ends of the reeds, and means for moving the sound-

box for the purpose of moving the reeds toward or from their operating mechanism.

5. In a musical instrument, the combination with a vertically-disposed sound-box having a sounding-board constituting its rear wall, of a horizontally-disposed sounding-board located within the sound-box, reeds mounted on the horizontal sounding-board and extended through and beyond the front side of the box, a sound-chamber partially inclosing the reeds and means for operating the reeds.

6. In a musical instrument, the combination with a sound-box having a sounding-board constituting the rear wall thereof, of a horizontal sounding-board located within the box, reeds mounted on the horizontal sounding-board and extended beyond the front side of the sound-box, a rearwardly-opening sound-chamber partially inclosing the reeds and opening into the sound-box, and reed-operating mechanism.

7. In a musical instrument, the combination with a vertically-disposed sound-box, and a sounding-board constituting the rear wall thereof, of a horizontal sounding-board located within the box and disposed in close relation to the vertical sounding-board, a series of reeds carried by the horizontal sounding-board and extended beyond the front of the sound-box, a semicylindrical sound-chamber supported by the horizontal sounding-board and having its open rear side disposed adjacent to the vertical sounding-board, and reed-operating mechanism located in front of the semicylindrical sound-chamber.

8. In a wireless piano, the combination with a vertically-disposed, tiltingly-mounted sound-box provided with a sounding-board constituting the rear wall thereof, of a series of reeds supported within the sound-box and terminating at one end adjacent to the sounding-board, reed-operating mechanism disposed to engage the front ends of the reeds, and means for tilting either portion of the sound-box.

9. In a musical instrument, the combination with a sound-box and a sounding-board constituting the rear wall thereof, of a sound-conductor mounted to the sounding-board and extended through the opposite wall of the box, a sound-chamber extended through the wall of the sound-box at a point below the sound-conductor and having its rear open side disposed adjacent to the sounding-board, a series of reeds partially inclosed by the sound-chamber, and means for operating the reeds.

10. In a musical instrument, the combination with a sound-box having a sounding-board constituting one wall thereof, of reeds mounted within the box and extended through the side thereof opposite the sounding-board, sympathetic sounding devices mounted on the sounding-board and within the box, and means for operating the reeds.

11. In a musical instrument, the combination with a sound-box, and a sounding-board constituting the rear wall thereof, of a series of reeds mounted within the box and extended through the sounding-board to a point in advance of the box, a semicylindrical sound-chamber partially inclosing the reeds and having a rear open side disposed contiguous to the sounding-board, and sympathetic sounding devices carried by the sounding-board within the box.

12. In a musical instrument, the combination with a sound-box, and a sounding-board constituting the rear wall thereof, of reeds extended laterally from the sounding-board, a semicylindrical sound-chamber partially inclosing the reeds and having an open side located adjacent to the sounding-board, a sound-conductor extending laterally from the sound-box at a point above the sound-chamber, and a series of sympathetic sounding devices mounted on the sounding-board within the box.

13. In a musical instrument, the combination with the reed-operating mechanism, of two separate series of reeds, and means for moving the series of reeds independently toward or from the reed-operating mechanism.

14. In a musical instrument, the combination with reed-operating mechanism, of reeds movable endwise toward or from the reed-operating mechanism, said reeds being divided into independently-movable series, and means for moving each series of reeds independently of the other series.

15. In a musical instrument, the combination with a sound-box composed of independently-movable sections, of reed-operating mechanism in spaced relation to the box, and a series of reeds mounted upon and movable with each section of the sound-box.

16. In a musical instrument, the combination with a sound-box composed of a pair of vertically-disposed independently-movable sections, the rear wall of each section being formed by a sounding-board, a series of horizontal reeds extended from within each of the sound-box sections, reed-operating mechanism disposed to engage the ends of the reeds, and means for effecting the independent movement of the sections of the sound-box.

17. In a musical instrument, the combination with a series of keys, and a series of resonant bars suspended above the same, of pivoted hammers arranged to strike the bars and each disposed to be directly engaged by a key, a series of reeds disposed end to end with the keys, and pickers extended from the rear ends of the keys and disposed to engage the reeds.

18. In a musical instrument, the combination with a series of keys, of a sounding-board located above the same, a series of resonant bars suspended from the sounding-board, a series of pivoted hammers arranged for direct actuation by the keys, means for moving the hammers alternately into or out of operative relation with the keys, a series of reeds disposed end to end with the keys, and pickers extending from the ends of the bars to engage the reeds.

19. In a musical instrument, the combination with keys and reeds disposed end to end, of pickers extending from the rear ends of the keys and disposed to engage the reeds.

20. In a musical instrument, the combination with a key, and a reed disposed beyond the rear end thereof, of a picker slidably mounted in the key, and means for automatically moving the picker to cause it to engage the reed during one movement of the key and to clear the reed during the opposite movement thereof.

21. In a musical instrument, the combination with a key provided with a guide in its rear end, of a picker movably mounted in the guide, means arranged to shift the picker longitudinally, and a reed disposed to be engaged by the picker during one movement of the key.

22. In a musical instrument, the combination with a key, a longitudinally-movable picker mounted in the rear end thereof, a cam-plate associated with the picker and extended above and below the same, reversely-curved guides disposed above and below the key for engagement with the cam-plate to shift the picker longitudinally in opposite directions during the opposite movements of the key, and a reed disposed beyond the key for engagement with the picker.

23. In a musical instrument, the combination with a key, a picker and a reed, of a cam-plate carried by the picker, a movable support having a cam-face disposed for engagement with the cam-plate, and means for adjusting the position of the support.

24. In a musical instrument, the combination with a key provided with a picker in its rear end, and a reed arranged for engagement by the picker, of movable supports disposed above and below the key and having cam-faces, a cam-plate carried by the picker and disposed for engagement with the curved faces of the supports, and means for shifting the position of the supports.

25. In a musical instrument, the combination with a key, a picker operated thereby and a reed, of hinged supports located at opposite sides of the picker and provided with cam-faces, a cam-plate carried by the picker and having curved faces disposed for engagement with the cam-faces of the supports, means connecting the supports to insure their movement in unison, and an adjusting device connected with one of the supports to shift the position thereof.

26. In a musical instrument, the combination with the keys, pickers and reeds all disposed in substantially the same plane, of a series of metal strips laterally supported above the reeds and disposed for engagement with the free ends thereof, a series of resonant bars suspended above the keys, a series of pivoted hammers disposed below the resonant bars and having arms extended into engagement with the keys, means for moving the metal strips into and out of engagement with the reeds, and means for moving the several hammer-arms out of engagement with the keys.

27. In a musical instrument, the combination with a sound-box having a sounding-board constituting the rear wall thereof, of a sound-chamber extended through the front wall of the box, a series of reeds partially inclosed by the sound-chamber and extended into close relation to the sounding-board, muffling devices for the sounding-board and sound-chamber, respectively.

28. In a musical instrument, the combination with a sound-box having a sounding-board constituting the rear wall thereof, of a sound-chamber extended through the front wall of the box, a series of reeds partially inclosed by the sound-chamber and extended into close relation to the sounding-board, muffling devices for the sounding-board and sound-chamber, respectively, and a single pedal connected to both of said muffling devices.

29. In a musical instrument, the combination with a casing having a movable sound-opening front and reeds, of a sound-box located within the casing and having a sounding-board constituting the rear wall thereof, a curved sound-conductor extending from the sounding-board of the sound-box, through the front of the box and into close proximity to the sound-opening front, means for operating the reeds, and means for adjusting the position of the sound-opening front to increase or diminish the sound.

30. In a musical instrument, the combination with a pivoted key, of a picker projecting from the rear end thereof, and a reed covered at one end and having its free end in hinging relation with the picker.

31. In a musical instrument, a series of reeds, a series of keys each carrying a picker-arm to engage a reed, and means for adjusting the picker-arm with relation to the reed.

32. In a musical instrument, the combination with an adjustable sound-box carrying reeds, of keys disposed in front of the sound-box

pickers adjustable on the keys and arranged to engage the reeds, means for adjusting the sound-box, and other means for adjusting the picker-arms upon the keys, whereby the engagement of the arms with the reeds may be adjusted by the movement of both the reeds and arms.

33. In a musical instrument, the combination with an adjustable sound-box carrying a series of reeds mounted therein, of a sound-conductor extending from the box, means located in the sound-box for producing sympathetic tones in consonance with those of the reeds, a semicylindrical sound-chamber partially inclosing the reeds, means for operating the reeds, and means for moving the sound-box toward and from the reed-operating means.

34. In a musical instrument, the combination with a sound-box having a sounding-board constituting the rear wall thereof, of a series of reeds having their rear ends located contiguous to the sounding-board, a sound-chamber partially inclosing the reeds, and reed-operating mechanism disposed to engage the front ends of the reeds.

35. In a musical instrument, the combination with a key, and a reed, of a picker extending from the rear end of the key for movement therewith and having limited independent movement, a cam for automatically effecting such independent movement of the picker when the key is depressed, and means for adjusting the position of the cam to regulate the extent of the engagement of the picker with the reed during the movement of the key.

699,841. ELECTRIC SIGNAL DEVICE. THOMAS J. ROOPER, Carleville, Ill. Filed Sept. 20, 1901. Serial No. 74,708. (No model.)

Claim.—1. In an electric signal device, the combination with a railway-track, of a semaphore, a signal-station, an automatic circuit-closing device in line with said semaphore and signal-station for closing the circuit through the same when said track is injured, and means for cutting said signal-station out of said circuit.

2. In an electric signal device, the combination with a railway-track, of a semaphore, an automatic circuit-closing device in line with said semaphore for closing the circuit through the same when said track is injured, a second semaphore, and automatic means carried by said first-named semaphore for closing the circuit through said second semaphore.

3. In an electric signal device, the combination with a railway-track, of a semaphore, an automatic circuit-closing device in line with said semaphore for closing the circuit through the same when said track is injured, a semaphore-arm, means for moving said arm by the closing of said circuit, an electric lamp carried by said semaphore, and means for closing the circuit through said lamp, said means being operated by the passage of the current through said semaphore.

4. In an electric signal device, the combination with a railway-track, of a signal-station, an automatic circuit-closing device in line with said signal-station for closing the circuit through the same when said track is injured, a signal in said station, a source of electrical supply, and means

for short-circuiting said source of electrical energy through said signal, said means being actuated by the passage of the current through said signal-station.

5. In an electric signal device, the combination with a railway-track, of a semaphore, an arm for said semaphore, gearing for operating said arm, a weighted lever for actuating said gearing, means for locking said gearing, a magnet for releasing said lever and an automatic circuit-closing device for closing the circuit through said magnet when the track is injured.

6. In an electric signal device, the combination with a railway-track, of a semaphore, an arm for said semaphore, a weighted lever for moving said arm, a magnet for releasing said lever, an automatic circuit-closing device for closing the circuit through the magnet when said track is injured, a second semaphore, an automatic means for closing the circuit through said second semaphore, said means being operated by the movement of said lever.

7. In an electric signal device, the combination with a railway-track, of a semaphore, an arm for said semaphore, a weighted lever for moving said arm, a magnet for releasing said lever, an automatic circuit-closing device for closing the circuit through said magnet when said track is injured, an electric lamp carried by said semaphore, a switch for closing the circuit through said lamp, means for closing said switch by the movement of said weighted lever, a second semaphore, and means also actuated by the movement of said lever for closing the circuit through said second semaphore.

8. In an electric signal device, the combination with a railway-track, of a signal, a circuit leading through said signal, a casing, a pair of contact-springs carried by said casing, one of said springs being connected to each side of the circuit, a member for electrically connecting said contact-springs, and means for moving said springs and member relatively when the track is injured.

9. In an electric signal device, the combination with a railway-track, of a signal, a circuit leading through said signal, a pair of casings, two contact-springs in each of said casings, one spring in each casing being connected to one side of the circuit, and the other spring to the other side of the circuit, members for electrically connecting the said pairs of springs, and means for moving said springs and member relatively when the track is injured.

699,842. REVERSIBLE GUARD-FINGER CLAMP FOR BRAKE-BEAMS. CHARLES F. HERRON, Chicago, Ill., assignor to Chicago Railway Equipment Company, Chicago, Ill., a Corporation of Illinois. Filed Feb. 13, 1902. Serial No. 94,656. (No model.)

Claim.—1. A guard-finger clamp for brake-beams formed with a plurality of sockets for the reception of the guard-finger and a cast for a member of the brake-beam, and means for clamping the guard-finger in either of said seats and coincidentally securing the device in position on a brake-beam member; substantially as described.

2. A guard-finger clamp for brake-beams consisting of jaws connected at one end, and being provided with an overhang having one free end, said overhang being designed to embrace the guard-finger; substantially as described.

3. A guard-finger clamp for brake-beams consisting of two jaws connected at one end, and a curved extension free at one end and provided with an opening in its free end for the passage of a bearing-bolt, said curved extension being designed to embrace the guard-finger; substantially as described.

4. A guard-finger clamp for brake-beams consisting of two jaws connected at one end, whereby a guard-finger may be secured in position in either of said curved extensions and the device coincidentally clamped in position on a brake-beam member; substantially as described.

5. A guard-finger clamp comprising two jaws connected at one end and having seats for embracing a brake-beam member between their

free ends, and overhanging heads extending from the edges of said jaws and provided with aligning openings in their free ends, either opening being capable of receiving a guard-finger; substantially as described.

6. A guard-finger clamp for brake-beams consisting of two jaws connected at one end and formed with seats at their opposite or free ends, overhanging heads extending from the edges of said jaws and being provided with perforated lugs at their free ends, and hollow beams formed on said jaws in alignment with the perforated lugs on said overhanging heads; substantially as described.

7. A guard-finger clamp having a plurality of sockets whereby said clamp may be secured in position at either end of the beam, and a reversible guard-finger clamp; substantially as described.

8. A guard-finger clamp having jaws for attachment to the beam, and a plurality of clamp bolts or pins, either of which is adapted to hold a guard pin or finger; substantially as described.

9. A guard-finger clamp consisting essentially of two members having parallel folds for separately cooperating with the guard pin or finger; substantially as described.

10. A guard-finger clamp consisting essentially of two members each of which is provided with a fold or ear, said folds or ears being in vertical alignment and designed to separately cooperate with a guard pin or finger; substantially as described.

699,843. MACHINE FOR END-MARKING SHEET-METAL BOULDS. WILLIAM J. HENRY, Chicago, Ill., assignor to one-half to WILLIAM J. HENRY, Chicago, Ill. Filed Apr. 12, 1901. Serial No. 15,707. (No model.)

Claim.—1. A machine for the purpose stated comprising a die or support, vertically-reciprocating forming-jaws, and means for moving said jaws inwardly against a body-blank while said jaws are descending, said support being mounted to move in unison with the jaws in a part of the vertical reciprocation thereof.

2. A machine for the purpose stated, comprising a die or support, vertically-reciprocating wings pivoted to swing in vertical planes, forming-jaws carried by said wings, and means for moving said jaws inwardly against a body-blank while said jaws are descending, said support being mounted to move in unison with the jaws in a part of the vertical reciprocation thereof.

3. A machine for the purpose stated, comprising a die or support, vertically-reciprocating wings pivoted to swing in vertical arcs, and forming-jaws carried by said wings and sliding horizontally therein radially toward a centrally-located body-blank.

4. A machine for the purpose stated, comprising a die or support, vertically-reciprocating wings pivoted to swing in vertical arcs, forming-jaws carried by said wings and movable horizontally therein, and springs applied to said jaws which tend to retract the jaws from their work.

5. A machine for the purpose stated, comprising a die or support, vertically-reciprocating wings pivoted to swing in vertical arcs, forming-jaws carried by said wings and movable horizontally therein, said jaws being each made of a plurality of parts having relative horizontal movements.

6. A machine for the purpose stated comprising a die or support, vertically-reciprocating forming-jaws adapted to surround said die or support, and a cam-ring through which said jaws pass in their descent, said ring being adapted to engage at its inner margin the jaws to move the jaws inwardly toward the die or support as the jaws descend.

7. A machine for the purpose stated comprising a die or support, vertically-reciprocating wings pivoted to swing in vertical arcs, forming-jaws carried by said wings, and a cam-ring through which said jaws pass in their descent, said ring being constructed to move said jaws inwardly as the wings descend.

8. A machine for the purpose stated, comprising a die or support, vertically-reciprocating forming-jaws, a cam-ring adapted to engage the jaws to move the same inwardly as the jaws descend, and springs applied to throw the jaws outwardly when disengaged from said cam-ring.

9. A machine for the purpose stated, comprising a die or support, vertically-reciprocating forming-jaws, a cam-ring adapted to engage the jaws to move the same inwardly as the jaws descend, and a cam-ring constructed to move said jaws inwardly in the descent of the head.

10. A machine for the purpose stated, comprising a die or support, a vertically-reciprocating forming-head, jaws carried by said head, means for moving said jaws inwardly against a body-blank in the descent of the head, and a head-plate adapted to enter a depression in the end plate of the blank against the margins of which the jaws act, said head-plate being non-rotative and having a continuous margin against which the jaws act.

11. A machine for the purpose stated, comprising a die or support, radially-movable forming-jaws, and a collapsible head-plate adapted to press upon the end plate of the blank-body and against the margins of which the jaws act.

12. A machine for the purpose stated, comprising a die or support, a vertically-reciprocating head, forming-jaws carried by said head, means for moving said jaws inwardly against a body-blank in the descent of the head, and a collapsible head-plate adapted to enter a depression in the end plate of the blank and against the margins of which the jaws act.

13. A machine for the purpose stated, comprising a die or support, radially-movable forming-jaws, and a segmental head-plate, the parts of which are hinged at their adjacent corners to a part which carries the jaws, and filling-pieces adapted to fill the space between the segments of the plate.

14. A machine for the purpose stated, comprising a die or support, a vertically-reciprocating head, jaws carried by said head, means for moving said jaws inwardly against a body-blank in the descent of the head, and a segmental head-plate, the parts of which are hinged at their adjacent corners to the head, and against the outer margin of which, when said plate is expanded, the forming-jaws act.

15. A machine for the purpose stated, comprising a die or support, a vertically-reciprocating head, forming-jaws carried by said head, means for moving said jaws inwardly against a body-blank in the descent of the head, a segmental head-plate, the parts of which are hinged at their adjacent corners to the head and against the outer margin of which, when the plate is expanded, the forming-jaws act, and filling-pieces projecting from the head and adapted to fill the space between the segments of the plate.

16. A machine for the purpose stated, comprising a die or support, radially-movable forming-jaws arranged alternately in two sets, the jaws of one set overlapping a part of the work effected by the jaws of the other set.

17. A machine for the purpose stated, comprising a die or support, radially-movable forming-jaws arranged alternately in two sets, the jaws of one set overlapping a part of the work effected by the jaws of the other set, and means for advancing the jaws of one set to their work and retracting the same before the jaws of the other set are advanced to their work.

18. A machine for the purpose stated, comprising a die or support, vertically and horizontally movable jaws arranged alternately in two sets, the jaws of one set overlapping a part of the work effected by the jaws of the other set, and means for moving said jaws inwardly against the work as the jaws are moved downwardly.

19. A machine for the purpose stated, comprising a die or support, a vertically-reciprocating forming-head, forming-jaws carried thereby, said jaws being divided in two sets and the jaws of one set being arranged alternately with respect to the jaws of the other set, said jaws of one set being actuated in advance of the jaws of the other set, and means for moving said jaws inwardly against the body-blank in the descent of the head.

20. A machine for the purpose stated, comprising a die or support, a vertically-reciprocating head, forming-jaws carried by said head, said jaws being arranged in two sets and the jaws of one set being arranged alternately with respect to the jaws of the other set, one set of said jaws being actuated in advance of the other, and the working faces of the jaws of one set overlapping a part of the work effected by the jaws of the other set.

21. A machine for the purpose stated, comprising a die or support, two sets of jaws which have vertical and horizontal movement, the working faces of one set of jaws overlapping a part of the work effected by the jaws of the other set, means for advancing said jaws to their work

and means for retracting one set of jaws from the work before the jaws of the other set are advanced.

22. A machine for the purpose stated, comprising a die or support, vertically and horizontally movable forming-jaws, arranged in two sets, the jaws of one set being arranged alternately with respect to the jaws of the other set, means for moving said jaws inwardly as they descend, said means being constructed to move one set of jaws inwardly to their work and retract the same before the jaws of the other set are advanced to their work.

23. A machine for the purpose stated, comprising a die or support, radially-movable jaws arranged in two sets, the jaws of one set being arranged alternately with respect to the jaws of the other set, means for moving one set of jaws horizontally to their work and retracting the same before the jaws of the other set are advanced to their work, and means for forcing the set of jaws first actuated against the work after the second set has been retracted.

24. A machine for the purpose stated, comprising a die or support, vertically and horizontally movable jaws arranged in two sets, the jaws of one set being arranged alternately with respect to the jaws of the other set, a cam-ring into which said jaws are depressed and by which they are advanced inwardly against the work, said cam-ring being provided with two sets of cams, one set being arranged above the other, whereby the two sets of jaws are separately actuated, as said jaws are moved downwardly.

25. A machine for the purpose stated, comprising a die or support, vertically and horizontally movable jaws arranged in two sets, the jaws of one set being arranged alternately with respect to the jaws of the other set, a cam-ring into which said jaws are depressed and by which they are advanced inwardly against the work, said cam-ring being provided with two sets of cams, one set being arranged above the other, whereby the two sets of jaws are separately actuated as said jaws are moved downwardly, the jaws of one set being passed entirely below the upper set of cams, and springs applied to said last-mentioned jaws to effect a prompt retraction of said jaws after they have passed below their actuating-cams.

26. A machine for the purpose stated, comprising a die or support, vertically and horizontally movable jaws arranged in two sets, the jaws of one set being arranged alternately with respect to the jaws of the other set, a cam-ring through which said jaws are depressed and by which they are advanced inwardly against the work, said cam-ring being provided with two sets of cams, one set above the other, whereby the two sets of jaws are separately actuated as said jaws are moved downwardly, the jaws of one set being passed entirely below the upper set of cams and springs applied to said last-mentioned jaws to effect a prompt retraction of said jaws after they have passed below their actuating-cams, the working faces of the jaws of the last-mentioned set being made wider than the space between the jaws of the other set when the latter jaws are moved inwardly.

27. A machine for the purpose stated comprising a die or support, combined gripping and forming jaws, and means causing said jaws to first grip a body-blank to hold it in place and thereafter to form a seam on said body-blank.

28. A machine for the purpose stated comprising a die or support, vertically-reciprocating, combined gripping and forming jaws, and means causing the gripping-jaws in the first part of the descent thereof to grip the body-blank to hold it in place and thereafter in the further descent of the jaws to move the forming-jaws inwardly to form a seam on the body-blank.

29. A machine for the purpose stated comprising a die or support, vertically-reciprocating, combined gripping and forming jaws, and means causing the gripping-jaws in the first part of the descent thereof to grip the body-blank to hold it in place and thereafter in the further descent of the jaws to move the forming-jaws inwardly to form a seam on the body-blank, said support being movable in unison with the jaws in a part of the vertical reciprocation of the latter.

30. A machine for the purpose stated comprising a die or support, vertically-reciprocating, combined gripping and forming jaws, means causing the gripping-jaws in the first part of the descent thereof to grip the body-blank to hold it in place, and thereafter in the further descent of the jaws to move the forming-jaws inwardly to form a seam on the body-blank, and a spring applied to hold each forming-jaw to retract it with respect to its associated gripping-jaw.

31. A machine for the purpose stated comprising a die or support, a plurality of vertically-reciprocating forming-jaws, adapted when depressed to surround said die or support, and means for moving said jaws inwardly against the body-blank while said jaws are descending, said jaws being each made of a plurality of parts having relative, horizontal movement radially toward the die or support.

699,844. NON-REVERSIBLE WATER-WHEEL. JOHN T. MOATE, Adelaide, South Australia, Australia. Filed Dec. 12, 1901. Serial No. 68,864. (No model.)

Claim.—1. An improved non-reverting water-wheel comprising a shaft, arms radiating therefrom, vanes hinged to said arms and chains connected with the vanes for limiting the movement thereof, said vanes comprising semicylindrical strips of metal arranged parallel with spaces between them and bars carrying the said strips, substantially as described.

2. In combination in a water-wheel, a vertical shaft, a bottom section having vanes and attached rigidly to the said shaft, a section superimposed above the rigid section and having vanes and float-operated means for connecting said superimposed section with and disconnecting the same from the said shaft, substantially as described.

699,845. COMBINATION-LOCK. WILLIAM H. S. MOORE, West Chicago, Ill. Filed Jan. 22, 1901. Serial No. 45,195. (No model.)

Claim.—1. The combination with rotary tumblers and a locking-bolt, of means for disengaging the tumblers simultaneously with the retraction of the locking-bolt from its keeper, substantially as set forth.

2. In a combination-lock, the combination of rotary tumblers, actuated by rotary dial, a slide adapted to throw back the latch-bolt and simultaneously rotate the tumblers, and a pawl adapted to release both the slide and the tumblers after the tumbler-locks have been set in registry with the free end of each pawl, substantially as shown and described.

3. In a combination-lock, the combination of rotary tumblers, each provided with one or more tumbler-locks, each tumbler actuated by a rotary graduated dial, a slide carrying a pivoted pawl, a stationary cam adapted to raise each pawl through the tumbler-locks brought into registry with the free end of the pawl, a spring adapted to hold the pawl against the cam, a projection from the slide adapted to engage and throw back the latch-bolt of the lock, projections from the slide adapted to strike against projections from the rotary tumblers so as to irregularly rotate each tumbler, a latch-knob actuating the said slide, and means for changing the relation of the dial and tumblers in respect to the graduations on the dial, substantially as shown and described.

4. In a combination-lock, the combination of rotary tumblers actuated by rotary dial, means whereby the complete unlocking of the lock causes such rotation of the tumblers as to return them to a locked position, interlocking concentric sleeves connecting the rotary tumblers with the rotary dial, and a series of pin-holes in the outer flanges of the said sleeves, each pin-hole being adapted to receive a pin fixed in the under face of the dial so as to permit the graduations on the dial to be set in various relations to the notches of the rotary tumblers, substantially as shown and described.

699,846. HORSE-DETACHER. CHARLES J. MEYER, Charleston, W. Va. Filed Feb. 17, 1902. Serial No. 94,881. (No model.)

Claim.—1. In a horse-detacher, the combination of a pivotally-mounted flexible coupling-pin, a draft element held on and by said pin and adapted to slide from the pin when the latter is straightened out forwardly, means to engage the outer end of said pin when the same is turned

rearwardly, and means to lock and release said pin-engaging means, substantially as described.

2. In a horse-detacher, the combination of a pivotally-mounted, flexible coupling-pin, a draft element pivoted thereon and adapted to be drawn therefrom when the coupling-pin is straightened out forwardly, a hook to engage the pin, to lock the latter against pivotal movement and retain the draft element thereon, a stop, coacting with the hook to maintain the engagement of the latter with the flexible pin, and a movable keeper to engage and disengage the hook, substantially as described.

3. In a horse-detacher, the combination of a pivotally-mounted coupling-pin having an outer section flexibly connected and adapted to be disposed at an angle thereto, a draft element on said pin and adapted to be drawn therefrom when said pin is turned forwardly, the said outer section of the pin having an opening, a pivotally-mounted hook to engage said opening and lock the pin in position to retain the draft element, and a movable keeper to engage and disengage said hook, substantially as described.

699,847. COLLAR-FOUNDATION. RABBIT & FURBER, New Britain, Conn. Filed Oct. 22, 1901. Serial No. 79,999. (No model.)

Claim.—1. A reinforce for collars, coats, and the like, comprising a central field of fabric having hairs woven therewith, with a binding of leather-like material impervious to and covering the ends of the hair-like portion of said fabric.

2. A collar-foundation formed of the body part of hair cloth A bound with leather B, substantially as and for the purpose specified.

3. A collar-foundation formed of a body part of hair cloth bound at the upper and lower edges with leather and reinforced at the ends.

4. A collar-foundation formed of a body part of hair cloth and bound at the upper and lower edges with leather, the hair at the central portion of the collar being substantially perpendicular to the edges and at the ends reinforced by hair cloth for the purpose specified.

5. A reinforce for collars, coats, and the like, comprising a central field of fabric having hairs woven therewith, with a binding of a material impervious to, and covering, the ends of the hairs in said fabric.

699,848. SEALING DEVICE FOR TUBULAR WELLS. CHARLES F. FENELAN, Cincinnati, Ohio, assignor to the Procter-Greer Manufacturing Co., Cincinnati, Ohio, a Corporation of Ohio. Filed July 5, 1891. Serial No. 57,555. (No model.)

Claim.—1. In a sealing apparatus of the character indicated, the combination of an expandable seal, a rotatable compressor operative thereon, and a single tube supporting the seal and also engaging and operating the compressor said tube detachably secured to the compressor and said compressor remaining attached to the seal when the tube is removed.

2. In a sealing apparatus of the character indicated, the combination of a single tube, an independent expandable seal, and a compressor on the seal, adapted to be directly detachably secured to, and operated by the tube, whereby the tube may be removed and the seal and compressor left in place.

3. In a sealing apparatus, the combination of a cylindrical expandable seal having a threaded central stem, and a rotating compressor operative thereon, a depending-tube adapted to be detachably and rotatively connected to said compressor, and expandable and contractible means for connecting or disconnecting the same at will.

4. In a sealing apparatus of the character indicated, the combination of the expandable seal, and its rotating compressor having an upward tubular flange; a depending-tube adapted to drop down within the flange of the compressor; radial pins attached to and extending through the depending-tube; a conical or wedge-shaped "plunger" carried within the depending-tube adapted to be dropped down between the inner ends of the radial pins and force them outward through corresponding apertures of the compressor-flange; and springs coiled upon the pins and acting normally to withdraw them inward and disengage the tube and flange when the plunger is withdrawn upward, substantially as set forth.

5. In a sealing apparatus of the character indicated, the combination of a seal having a threaded stem; a compressor on said stem; a tube; and radially-opening devices between the tube and compressor whereby the seal is detachably secured and the expander operated.

699,849. APPARATUS FOR SINKING TUBULAR WELLS. CHARLES F. FENELAN, Cincinnati, Ohio, assignor to the Procter-Greer Manufacturing Co., Cincinnati, Ohio, a Corporation of Ohio. Filed Aug. 27, 1901. Serial No. 73,645. (No model.)

Claim.—1. In a well-sinking apparatus a rectangular supporting-frame composed of an upper and lower series of horizontal tubular ribs connected by vertical tubular uprights united thereto by "pipe-fittings" and with corner-uprights extended above the uppermost horizontal ribs, in combination with the derrick consisting of two side pieces, one at each side of the frame and provided with fittings extending in the direction of the length of the said side pieces and provided with terminal studs, said forward-extended corner-uprights having sockets to receive said studs when the derrick is in its elevated position, and said fittings pivotally mounted in said forward uprights substantially as set forth.

2. In a well-sinking apparatus, a rectangular tubular supporting-frame substantially as described and including corner-uprights, in combination with a derrick composed of two side members converging upward and having fittings at their lower ends and forming longitudinal extensions of said ends one of said side pieces pivotally mounted to each of the corner-uprights of the main frame and said fittings having terminal studs to fit sockets in the upper extremities of the front uprights, when the derrick is in elevated position, a walking-beam having one end pivotally connected to the extended portions of the rear corner-uprights and extending forward between the extended portions of the front uprights substantially as set forth.

3. In a well-sinking apparatus of the character indicated, the combination with a frame composed of horizontal spaced metallic tubes and means uniting them at the ends, and tubular corner-posts, of a shaft-support consisting essentially of a triangular block on each of a pair of tubes and having a journal-bearing at the apex and perpendicular to the plane of the triangle, a groove at the base and in the plane of the triangle and one or more correspondingly-grooved tubes removably united thereto with screws or bolts to constitute a clamp connection for the shaft-support upon a tubular rib or upright of a frame, substantially as set forth.

4. The combination with a main frame having sockets at the front, of a removable "revolving-head" device embodying a frame containing the revolving head, said last-named frame fixed to bars or tubes adapted to telescope into said sockets of the main frame, a driving-shaft engaging the revolving head by bevel-gearing and clamping-caps adapted to secure the device removably upon ribs or extensions of the main supporting-frame of the well-sinking apparatus, substantially as set forth.

699,850. MEANS FOR ACTUATING WINDOW-BLINDS. DANIEL W. BARNES, Worcester, Mass. Filed Dec. 21, 1901. Serial No. 95,588. (No model.)

Claim.—1. In a mechanism for actuating window-blinds movably mounted on an overhead track, upon which said blind may slide or be swung outwardly and form an awning the combination of said track, blind, actuating mechanism extending to the interior of the house connected with said blind to open and close said blind and allow blind to swing outwardly without disengaging from house or blind the said actuating mechanism, and a locking device secured to the said blind for normally holding blind in vertical position when not swung outwardly, capable of disengagement from a part secured on house to allow said blind to be swung outwardly as shown and described substantially.

2. The combination with actuating mechanism having a shaft extending into the interior of the house and actuating-arm having one or more connectors and pivots thereon and adapted to connect to a blind for opening and closing said blind, of a blind having rollers adapted to turn about on an overhead track, as overhead track adapted to allow the blind to be swung outwardly to form an awning and on which it may slide to open or close the blind, and two-part locking device one part secured to the house, the other part secured to the said blind for normally holding blind in vertical position when not swung outwardly, capable of disengagement from part secured on house to allow the blind to be swung outwardly, substantially as shown and described.

699,851. APPARATUS FOR FUSED-BATH ELECTROLYTES. CHARLES W. BARNES and GEORGE P. BARNES, Philadelphia, Pa.; said Charles W. Barnes assignor to said George P. Barnes. Filed Aug. 20, 1900. Renewed Oct. 15, 1901. Serial No. 73,693. (No model.)

Claim.—1. In an apparatus for the electrolysis of fused substances, the combination of a vessel for containing fusible substances; a heating-chamber of smaller dimensions than said vessel, but of which a portion of said vessel forms the bottom, and means to said heating-chamber for reducing the contents of said vessel to fusion; a partition forming one of

the said walls of the heating-chamber which extends below the normal level of the fused contents of said vessel but does not reach to its bottom; an electrolytic chamber outside but immediately alongside of the heating-chamber separated from it only by said partial partition, there being no uncontrolled air-space between the two; and means consisting of positive and negative electrodes situated within said electrolytic chamber, and wholly exterior to the heating-chamber, for carrying on the electrolysis of the fused contents of the vessel.

2. In an apparatus for the electrolysis of fused substances, the combination of a heating-chamber in the form of a reverberatory furnace; a vessel for containing fused substances over which the products of combustion in the reverberatory furnace play, said fusion vessel extending at one side of the heating-chamber beyond its walls; a partition forming the last-mentioned side of the heating-chamber which extends below the normal level of the contents of said fusion vessel but which does not reach to its bottom; and means for conducting electrolysis of the contents of said fusion vessel situated wholly outside of said partial partition, substantially as described.

3. In an apparatus for the electrolysis of fused substances, the combination of a heating-chamber in the form of a reverberatory furnace; a vessel for containing fused substances over which the products of combustion in the reverberatory furnace play, said fusion vessel extending at one side of the heating-chamber beyond its walls; a partition forming the last-mentioned side of the heating-chamber which extends below the normal level of the contents of said fusion vessel but which does not reach to its bottom; a separate electrolytic box open at the bottom and carrying positive and negative electrodes and fitting removably into that part of the fusion vessel which is situated outside of the heating-chamber, substantially as described.

4. In an apparatus for the electrolysis of fused substances, the combination of a fusion vessel; means whereby products of combustion are caused to play over the surface of all but a restricted portion of the contents of said fusion vessel; one or more vertical partitions extending below the normal level of the contents of said fusion vessel wholly insulating the said restricted portion of the contents of said fusion vessel from the products of combustion whereby free access to said restricted portion may be had; a removable electrolytic box, open at the bottom, carrying positive and negative electrodes; and means for bringing said electrolytic box into or out of contact with the contents of the fusion vessel within said restricted portion, substantially as described.

5. In an apparatus for the electrolysis of fused substances, the combination of a fusion vessel and means for heating the contents thereof; a separate electrolytic box, open at the bottom, and carrying attached to itself both positive and negative electrodes; and means for placing said electrolytic box within a portion of said fusion vessel with its bottom dipping beneath the contents thereof and removing it therefrom, substantially as described.

6. In an apparatus for the electrolysis of fused substances, the combination of a fusion vessel; means for heating its contents; a separate electrolytic box open at the bottom removable therefrom carrying positive and negative electrodes and having hollow walls with means for maintaining circulation of a suitable fluid medium through said walls, substantially as described.

7. In an apparatus for the electrolysis of fused substances, the combination of a fusion vessel; vertical partitions extending below the normal level of the contents of the fusion vessel and dividing it into a centrally-located heating-chamber and a series of electrolytic chambers grouped around said heating-chamber; means situated within said heating-chamber for heating the contents of the fusion vessel; and a series of electrodes situated wholly within said electrolytic chamber whereby electrolysis may be carried on therein, substantially as described.

8. In an apparatus for the electrolysis of fused substances, the combination of a fusion vessel; means for heating the contents of said vessel; a preheating-chamber within the effective reach of the source of heat provided with a bottom above the normal level of the contents of the fusion vessel into which the contents of the preheating-chamber when fused will flow down; and electrodes immersed in the contents of the fusion vessel, substantially as described.

9. In an apparatus for the electrolysis of fused substances, the combination of a fusion vessel; means for heating its contents; a removable open-bottomed electrolytic box carrying electrodes, fitting into the fusion vessel; and ledges on the side of the fusion vessel below the normal level of its contents upon which the electrolytic box rests and which are arranged to seal the outside of the box from the contents of the fusion vessel, substantially as described.

10. In an apparatus for the electrolysis of fused substances, the combination of the fusion vessel; means for heating its contents; an open-bottomed removable electrolytic box carrying electrodes; and blocks of fire-clay, or similar resistant material, fitted removably around the inside

of the electrolytic box and forming the lining thereof, substantially as described.

11. In an apparatus for the electrolysis of fused substances, the combination of a fusion vessel; two vertical partitions extending below the normal level of the contents of the fusion vessel, but not reaching to its bottom, forming three separate chambers above the fusion vessel, one at each end and one in the center; means situated within each of the end chambers for heating the contents of the fusion vessel; and one or more open-bottomed electrolytic boxes carrying electrodes fitted removably within the central chamber, substantially as described.

699,853. SHAFT-FURNACE FOR BURNING CEMENT. JOHANN A. F. C. SCHNEIDER, Lagerdorf, Germany. Filed July 27, 1900. Serial No. 25,081. (No model.)

Claim.—In combination in a furnace, a drying-chamber, heating and protecting chambers above and below said drying-chamber and opening thereto, a combustion-chamber, a preliminary-heating chamber into which the hot gases from the combustion-chamber pass, and a heating and protecting chamber lying back of the drying-chamber and connecting the preliminary-heating chamber with the chamber below the drying-chamber, the gases passing therethrough in a downward direction, substantially as set forth.

699,858. ANTI-OFFSET DEVICE. RALPH C. DETHMERS, South Orange, N. J., assignor to C. B. Ottrell & Sons Company, New York, N. Y., a Corporation of New Jersey. Filed Dec. 10, 1901. Serial No. 25,251. (No model.)

Claim.—1. The combination with a roller in contact with which a printed web passes, of a self-adjusted roller in contact with the first-mentioned roller for taking the offset therefrom, a brush and a lever by which

said brush is carried for taking it into and out of contact with said soft-surfaced roller, substantially as and for the purpose herein described.

2. The combination with a roller in contact with which a printed web passes, of a soft-surfaced roller in contact with the first-mentioned roller for taking the offset therefrom, a brush normally out of contact with said soft-surfaced roller, and means for bringing said brush from time to time in contact with said soft-surfaced roller, substantially as herein described.

3. In a folding-machine, the combination of a plurality of folding or turning devices each for folding or turning a printed web, offset-receiving rollers in contact with which severally the printed webs pass, soft-surfaced wiping-rollers one for each folding or turning device in contact with its offset-receiving roller or rollers, rock-shafts and attached cleaning-brushes one for each of said wiping-rollers, connections between said rock-shafts and means applied to one of said rock-shafts for placing the several brushes together into and out of contact with their respective wiping-rollers, substantially as herein described.

699,854. PRINTING-PRESS ATTACHMENT. EDWARD C. KIMMEL, Akron, Ohio, assignor to the Federal Appliance and Manufacturing Company, Pittsburg, Pa. Filed June 6, 1901. Serial No. 62,422 (No model.)

Claim.—1. Newspaper-casing mechanism comprising supports arranged at opposite sides of the path of a web and extending transversely thereof, and casing mechanism including cooperating devices for the opposite surfaces of the web, said cooperating devices being longitudinally adjustable on said supports, whereby the web may be operated upon at any desired point between its longitudinal edges.

2. Newspaper-casing mechanism comprising supports arranged at opposite sides of the path of the web and extending transversely thereof, and casing mechanism including cooperating rotating devices for the opposite surfaces of the web, said cooperating rotating devices being longitudinally adjustable on said supports, whereby the web may be operated upon at any desired point between its longitudinal edges.

3. Newspaper-casing mechanism comprising rotatable shafts arranged at opposite sides of the path of the web and extending transversely thereof, and casing mechanism including cooperating rotating devices at opposite sides of the web and adjustable longitudinally of the shafts and actuated thereby, whereby the web may be operated upon at any desired point between the longitudinal edges thereof.

4. The combination of a press-frame, two rotatable shafts extending transversely across the frame at opposite sides of the path of the web, a transverse support in the frame paralleling the shafts, and casing mechanism including cooperating rotating devices adjustable longitudinally of the shafts and support, the said rotating devices being mounted on and actuated by the shafts, whereby the web may be operated upon at any desired point between the longitudinal edges thereof.

5. The combination of a press-frame, two rotatable shafts extending transversely across the frame on opposite sides of the path of the web, the fixed guide extending transversely across the frame and paralleling said shafts, a frame adjustable longitudinally on said guide and on one of said shafts and adapted to be fixed to the said guide, casing mechanism consisting in part of a roll within said frame and mounted on the frame-supporting shaft and adjustable longitudinally with the frame, a second roll adjustable on the other shaft and adapted to cooperate with the first-mentioned roll, and paste-delivering mechanism carried by the said longitudinally-adjustable frame, substantially as shown and described.

6. Newspaper-casing mechanism embodying a rotating device formed with a peripheral opening, a paste-delivering device carried by the rotating device adjacent said opening, an isolating or covering device carried by the rotating device and operative through the peripheral opening thereof, and a cooperating surface at the opposite side of the path of the web for said rotating device, substantially as shown and described.

7. Newspaper-casing mechanism embodying a rotating device formed with a peripheral opening, a paste-delivering device carried by the rotating device and overhanging the peripheral opening thereof, an isolating or covering head operative through said peripheral opening and adapted

to embrace the paste-delivering device, actuating means for the head, and a cooperating surface at the opposite side of the web for said rotating device, substantially as shown and described.

8. Newspaper-casing mechanism embodying two cooperating rolls, means for driving said rolls at a peripheral speed equal to the speed of the web passing therebetween, a paste-delivering projection on the periphery of one of said rolls, a reciprocating head carried by said roll and having a top depression adapted to embrace the projection when the head is extended, and perforating-points carried by and projecting upwardly from the head, substantially as shown and described.

9. The combination of roll 14 formed with a peripheral opening, a perforating-head adapted to reciprocate through the opening, and the paste-applying block adapted to be positioned at either side of the opening, substantially as shown and described.

10. The combination of roll 14 formed with a peripheral opening and with peripheral depressions on opposite sides of the opening, and the paste-delivering block adapted to overhang the opening and projecting from a plate, said plate being adapted to be secured in either of the said roll depressions, substantially as shown and described.

11. Newspaper-casing mechanism comprising a rotating device formed with a peripheral opening, a paste-applying device adapted to be positioned at opposite sides of the opening, isolating or covering means operative through the opening, and a cooperating surface at the opposite side of the web for said rotating device.

699,855. ROTARY MEASURE. JOHN F. SCHNEIDER, Chicago, Ill. Filed May 2, 1901. Serial No. 60,230. (No model.)

Claim.—1. A measuring device comprising a frame or casing, a rotary, graduated measuring-wheel journaled in the casing and projecting therefrom for contact with the article to be measured, a dial on the casing, a pointer, concentric to said measuring-wheel, cooperating with said dial and capable of a step-by-step movement, means for locking said pointer from movement in either direction after each step of its movement and means on the measuring-wheel for first effecting the release of said locking means and thereafter moving said pointer one step.

2. A measuring device comprising a frame or casing, a rotary, graduated measuring-wheel journaled in the casing and projecting therefrom for contact with the article to be measured, a dial on the casing, a pointer, concentric to said measuring-wheel, cooperating with said dial and capable of a step-by-step movement, means for locking said pointer from movement in either direction after each step of its movement, means on the measuring-wheel for first effecting the release of said locking means and thereafter moving said pointer one step and means independent of the measuring-wheel for releasing said locking means to permit the pointer to be returned to zero.

3. A rotary measuring device comprising a frame or casing, a toothed wheel journaled therein, a dial on the casing, a pointer cooperating with the dial and rotating with said toothed wheel, a graduated measuring-wheel journaled in the casing concentrically to said toothed wheel and projecting from the casing for contact with the article to be measured, means for locking the toothed wheel from rotation and means on the measuring-wheel for first releasing the locking means and thereafter turning the toothed wheel one step, said locking means locking the toothed wheel from rotation in either direction after each step of its movement.

4. A rotary measuring device comprising a frame or casing, a toothed wheel journaled therein, a dial on the casing, a pointer cooperating with the dial and rotating with said toothed wheel, a graduated measuring-wheel journaled in the casing concentrically to said toothed wheel and projecting from the casing for contact with the article to be measured, means for locking the toothed wheel from rotation, means on the measuring-wheel for first releasing the locking means and thereafter turning the toothed wheel one step, said locking means locking the toothed wheel from rotation in either direction after each step of its movement, and means independent of the measuring-wheel for releasing said locking means and permitting the pointer to return to zero.

5. A measuring device comprising a frame or casing, a rotary, graduated measuring-wheel, journaled in said casing and projecting therefrom for contact with the article to be measured, a dial on the casing, a pointer

cooperating with said dial and capable of a step-by-step movement, means for locking said pointer from movement in either direction after each step of its movement, means on the measuring-wheel for first releasing said locking means and thereafter moving said pointer one step, said measuring-wheel being free to return to zero, and means independent of the measuring-wheel for releasing the pointer-locking means to permit said pointer to be returned to zero.

6. A rotary measuring device, comprising a casing, a toothed wheel journaled therein, a dial on the casing, a pointer connected with the wheel and cooperating with the dial, a reciprocating plunger in the casing provided with a detent adapted to interlock with the teeth of said wheel, a rotary measuring-wheel journaled in the casing and projecting therethrough between said toothed wheel and plunger and adapted to engage said plunger to release the detent from said toothed wheel and thereafter turn said wheel.

7. A rotary measuring device, comprising a casing, a toothed wheel journaled therein, a dial on the casing, a pointer connected with the wheel and cooperating with the dial, a reciprocating plunger in the casing provided with a detent adapted to interlock with the teeth of said wheel, a rotary measuring-wheel journaled in the casing and projecting therethrough between said toothed wheel and plunger and adapted to engage said plunger to release the detent from said toothed wheel, and thereafter turn said wheel and means for restoring the locking means after said toothed wheel has been turned one step.

8. A rotary measuring device, comprising a casing, a toothed wheel journaled therein, a dial on the casing, a pointer connected with the wheel and cooperating with the dial, a reciprocating plunger in the casing provided with a detent adapted to interlock with the teeth of said wheel, a rotary measuring-wheel journaled in the casing and projecting therethrough between said toothed wheel and plunger, and projecting parts on said measuring-wheel adapted to engage said plunger to release the detent from said toothed wheel and thereafter turn said wheel one step, and a spring-pressed lever pivoted in the casing having an exposed finger-piece at one end and adapted to engage at its other end a projection on the plunger to release the detent thereof from the toothed wheel.

9. A rotary measuring device comprising a casing, a toothed wheel journaled therein, a dial on the casing, a pointer connected with the toothed wheel and cooperating with the dial, a reciprocating plunger in said casing at one side of the toothed wheel provided at one end with a detent adapted to engage the teeth of said toothed wheel and at its lower end with a laterally-directed arm, a rotary measuring-wheel journaled in the casing and projecting therethrough between the plunger and toothed wheel, and projecting parts on said measuring-wheel adapted to engage a projecting part on the arm to release the detent thereof from the teeth of the toothed wheel and to thereafter engage one of the teeth of said toothed wheel to rotate the latter one step.

10. A rotary measuring device, comprising a casing, a toothed wheel journaled therein, a dial on the casing, a pointer connected with the toothed wheel and cooperating with the dial, a reciprocating plunger in said casing at one side of the toothed wheel provided at one end with a detent adapted to engage the teeth of said toothed wheel, and at its other end with a laterally-directed arm, a rotary measuring-wheel journaled in the casing and projecting therethrough between the plunger and toothed wheel, and projecting parts on said measuring-wheel adapted to engage a projecting part of the arm to release the detent from the teeth of the wheel and to thereafter engage one of the teeth of said wheel to rotate the latter one step, said plunger being located in the path of the projection on the measuring-wheel to limit the reverse movement of the measuring-wheel, and a step in the casing adapted to receive the thrust of the arm of said plunger when the projection on the measuring-wheel is brought into engagement with the plunger in the reverse movement of said measuring-wheel.

11. A rotary measuring device, comprising a casing, a toothed wheel journaled therein, a dial on the casing, a pointer connected with the toothed wheel and cooperating with the dial, a reciprocating plunger in said casing at one side of the toothed wheel provided at one end with a detent adapted to engage the teeth of said toothed wheel and at its other end with a laterally-directed arm, a rotary measuring-wheel journaled in the casing and projecting therethrough between the plunger and toothed wheel, and projecting parts on said measuring-wheel adapted to engage a projecting part of the arm to release the detent thereof from the teeth of the toothed wheel and to thereafter engage one of the teeth of said wheel to rotate the latter one step, and a spring bearing against said arm to hold the detent of the plunger normally engaged with the toothed wheel.

12. A rotary measuring device, comprising a casing, a toothed wheel journaled therein, a dial on the casing, a pointer connected with the toothed wheel and cooperating with the dial, a reciprocating plunger in said casing at one side of the toothed wheel provided at one end with a detent adapted to engage the teeth of said toothed wheel and at its other end with a laterally-directed arm, a rotary measuring-wheel journaled in the

casing and projecting therethrough between the plunger and toothed wheel, and projecting parts on said measuring-wheel adapted to engage a projecting part of the arm to release the detent thereof from the teeth of the toothed wheel and to thereafter engage one of the teeth of said wheel to rotate the latter one step, a spring bearing against the arm to hold the detent of the plunger normally engaged with the toothed wheel, and means independent of the measuring-wheel for lifting said plunger against the action of said spring.

13. A rotary measuring device, comprising a casing, a toothed wheel journaled therein, a dial on the casing, a pointer connected with the wheel and cooperating with the dial, a reciprocating plunger in the casing provided with a detent adapted to interlock with the teeth of said toothed wheel, a rotary measuring-wheel journaled in the casing and projecting therethrough between said toothed wheel and plunger, projecting parts on said measuring-wheel adapted to engage said plunger to release the detent from the toothed wheel and thereafter rotate said toothed wheel one step, and a spring-pressed lever pivoted in the casing and having at one end a finger-piece projecting through a slot in the casing-wall and adapted to engage at its other end a projection on said plunger to release the detent from the toothed wheel, said lever being provided with flat extensions which cover the slot in the casing through which said finger-piece passes.

14. The combination with a relative toothed wheel, a spring-pressed plunger at the side thereof and parallel with the plane of the wheel, a detent on the plunger, adapted to interlock with the teeth of the wheel, an actuating-wheel having its periphery located between the toothed wheel and plunger and projecting on the actuating-wheel adapted to engage said plunger and the teeth of the toothed wheel respectively, whereby the plunger will be first raised to free the detent of the toothed wheel and said toothed wheel thereafter rotated.

15. The combination with a relative toothed wheel, a spring-pressed plunger at the side thereof and parallel with the plane of the wheel, a detent on the plunger adapted to interlock with the teeth of said wheel, an actuating-wheel having its periphery located between the toothed wheel and plunger, a laterally-directed arm on the plunger opposite the detent on said plunger and located at the margin of the tooth-wheel and projections on the actuating-wheel adapted to engage said arm to raise the plunger to release the detent from the toothed wheel, and thereafter rotate said wheel.

16. A measuring device comprising a frame or casing, a rotary graduated measuring-wheel journaled in the casing and projecting therefrom for contact with the article to be measured, a dial on the casing, a pointer cooperating with said dial and associated with mechanism having a step-by-step movement, means for locking said pointer from movement in either direction after each step of its movement and means on the measuring-wheel for first effecting the release of said locking means and thereafter positively engaging said pointer mechanism to move the pointer one step, said measuring-wheel being at other times operatively free from said pointer mechanism.

699,856. GAS FOR FURNING WATER. HERBERT SMITH, Brooklyn, N. Y. Filed Aug. 7, 1901. Serial No. 71,948. (No model.)

Claim.—1. In combination, with an upright can for freezing water, of a removable partition-frame composed of upright and transverse partitions, the transverse partitions being provided with apertures adjacent said upright partition, substantially as set forth.

2. A cellular partition-frame for an upright freezing-can, consisting of an upright partition centrally arranged in said can, and a plurality of transverse partitions, the transverse partitions being provided with apertures adjacent said centrally-arranged upright partition and approximately the center of the can, substantially as set forth.

3. The combination, with an upright can for freezing water, of a removable partition-frame of sheet metal, consisting of a central upright partition, a plurality of transverse partitions on each side of said upright partition, said transverse partitions having their outer ends adjacent the walls of said upright can, and apertures at their inner ends adjacent said central upright partition, substantially as set forth.

699,857. MANTLE-SUPPORT FOR GAS-BURNERS. ELMAN H. TANN, West Sussex, N. Y., assignor to the Tanno Mantle Support Company, Buffalo, N. Y., a Corporation of New York. Filed May 31, 1901. Serial No. 68,464. (No model.)

Claim.—1. A mantle-support for a gas-burner, comprising an upright rod or standard, and a head surrounding the same and composed of a plurality of independent wings extending outward from the rod, arranged lengthwise thereof and separated from each other throughout their length, thereby permitting a direct and uninterrupted ascent of the products of combustion on opposite sides of the wings, substantially as set forth.

2. A mantle-support for a gas-burner, comprising an upright rod or standard, and a head surrounding the same and composed of a plurality of independent longitudinal wings separated from each other throughout their length and having their lower portions gradually narrowed toward the lower ends of the wings, whereby the lower portions of the wings present upwardly-diverging edges which gently deflect the ascending gases laterally on opposite sides of the wings, substantially as set forth.

3. A mantle-support for a gas-burner, comprising an upright rod or standard, and a winged head tapered from its middle portion toward both ends and having its wings arranged lengthwise of the rod, substantially as set forth.

699,858. MACHINE FOR BENDING IRON—FLAT AND ANGLE. WILLIAM VOLLMER, Brooklyn, N. Y. Filed Aug. 2, 1901. Serial No. 72,794. (No model.)

Claim.—1. An improved bending-machine of the class described, comprising a bed-plate, a main operating-arm arranged to swing above the surface of the bed-plate, a former mounted upon the bed-plate, means for moving the former into and out of operative position with respect to the operating-arm, a guide between which and the former the stock is fed above the bed-plate into position for bending, and a supplemental operating-arm which is operated simultaneously with the main operating-arm to maintain the stock in proper condition during the bending operation.

2. An improved bending-machine of the class described, comprising a bed-plate, a guide mounted upon the bed-plate, a main operating-arm pivoted above the bed-plate, a former mounted upon the bed-plate, means for moving the former into and out of operative position with respect to the guide and the operating-arm, and a supplemental operating-arm pivoted to the former and arranged to be depressed upon the stock during the bending operation.

3. An improved bending-machine of the class described, comprising a bed-plate, a guide mounted thereon, an operating-arm seated in a cavity formed in the guide and pivoted above the bed-plate whereby the arm is in close engagement with the guide, a former mounted upon the bed-plate, and means for moving the former into and out of operative position with respect to the guide and arm.

4. An improved bending-machine of the class described, comprising a bed-plate, a guide mounted thereon and provided with a recess having its wall curved, an operating-arm having a rounded end fitting in said recess and pivoted in said bed-plate, a former mounted on said bed-plate, and means for moving said former into and out of operative position with respect to the guide and arm.

5. An improved bending-machine of the class described, comprising a bed-plate, a guide mounted thereon and provided with a recess having a curved wall, a cap-plate secured to said guide and extending over said recess, an operating-arm having a rounded end fitting in said recess and pivoted in said bed-plate and said cap-plate, a former movably mounted on said bed-plate, and means for moving said former into and out of operative position with respect to the guide and arm.

699,859. ENGRAVER'S RULING-MACHINE. FREDERICK WILSON, Brooklyn, N. Y. Filed July 27, 1901. Serial No. 69,989. (No model.)

Claim.—1. In an engraver's ruling-machine, the combination of a table, a longitudinal bar of U-shaped cross-section supported thereon and having the open face thereof to the front, parallel guideways provided at

the front edge of the top and bottom flanges of said bar, a longitudinal nut provided on the inner surface of the lower part of said bar, a tool-head adapted to reciprocate on said guideways, a shaft mounted in said tool-head, a pinion secured to the inner end thereof adapted to mesh with said nut, a crank for operating the same, a tool-socket vertically arranged on said tool-head, means for inwardly or outwardly adjusting said socket relatively to said tool-head, and a downwardly spring-actuated tool-spindle provided in said socket, substantially as set forth.

2. In an engraver's ruling-machine, the combination of a tool-head guided on suitable ways, means for reciprocating the same, a vertically-disposed tool-socket arranged on said tool-head, a tool-spindle provided therein, a spring provided in said socket for actuating said spindle, an elbow-lever pivoted to said tool-head and connected with the upper end of said spindle, a screw-out arranged in the upper end of said spindle adapted to adjust said spindle in vertical direction, and means for adjusting said socket inwardly or outwardly relatively to said tool-head, substantially as set forth.

3. In an engraver's ruling-machine, the combination, with a table having a side gage, of a tool-head, means for guiding and means for operating the same, a cutting-tool adjustably secured to said tool-head, a bar at one end pivotedly mounted on the table, and having a recessed opposite end, a suitable piece supported at the opposite end of the table and adapted to abutably support the recessed end of said bar, and a clamping means adapted to slide on said bar, substantially as set forth.

4. In an engraver's ruling-machine, the combination, with a table having a side gage, of a tool-head, means for guiding and means for reciprocating the same, an adjustable cutting-tool secured to said tool-head, an adjustable clamping means secured to said table, and on inwardly and outwardly adjustable and spring-actuated edge gage secured to said table, substantially as set forth.

5. In an engraver's ruling-machine, the combination, with a table having a side gage, of a tool-head, means for guiding and means for reciprocating the same, a cutting-tool secured to said tool-head, a clamping means secured to said table, a downwardly spring-actuated edge gage, movable supports on the frame of said table for pivotedly securing said edge gage, and means for reciprocating said supports, substantially as set forth.

699,860. STRAIN-WAGON TRUCK. PAUL H. WHITE, Indianapolis, Ind., assignor to White Steam Wagon Company, Indianapolis, Ind., a Corporation of Indiana. Filed Nov. 27, 1901. Serial No. 68,821. (No model.)

Claim.—1. A truck for wagons, consisting of a single axle, and an open frame carried by said axle above the same, the said open frame being adapted for attachment to the main frame of a wagon so as to receive a projected portion thereof.

2. A truck for wagons, consisting of a single axle, a pair of springs carried by said axle, one near each end, and an open frame mounted upon said springs above the axle, the said frame being adapted to be attached

to the main frame of a wagon and to receive a projected portion of the said main frame.

3. The combination with a wagon-frame, of a boiler-furnace carried by the wagon-frame and projected below the same, an open frame surrounding the projecting portion of the furnace, wheel-supports carried by opposite sides of the open frame, and connections between the open frame and wagon-frame.

4. The combination with a wagon-frame, of a boiler-furnace carried by the frame and projected below the same, an open frame surrounding the projecting portion of the furnace, an axle extending transversely beneath the open frame, spring connections between the open frame and axle, and connections between the open frame and wagon-frame.

5. The combination with a wagon-frame, of a boiler-furnace carried by the wagon-frame and projected below the same, an open frame surrounding the projected portion of the furnace, a pivotal connection on a longitudinal axis between the wagon-frame and open frame, and wheel-supports carried by the open frame.

6. The combination with a wagon-frame, of a boiler-furnace carried by the wagon-frame and projected below the same, an open frame surrounding the projected portion of the furnace, a pivotal connection on a longitudinal axis between the wagon-frame and open frame, an axle below the open frame, and spring connections between the axle and open frame.

7. The combination with a wagon-frame, of a boiler-furnace carried by the wagon-frame and projected below the same, a truck mounted below the projected portion of the furnace, and a longitudinal pivotal connection between the truck and the wagon-frame in line with the projected portion of the furnace.

699,861. RAIL. ALAN WINDHAMMER, Chicago, Ill., assignor to American Key Can Company, Chicago, Ill., a Corporation of Illinois. Filed Mar. 21, 1901. Serial No. 88,166. (No model.)

Claim.—The combination with a rail, of a bell embracing a central curved portion so shaped as to bear throughout its length against the outer surface of the rail when the bell is in a downwardly-inclined position, and provided with approximately straight parallel end portions having hooks for engagement with sockets in the bell-cars on said rail, said parallel end portions being arranged at a distance apart approximately equal to the external diameter of the upper part of the rail, and oblique portions joining the ends of the curved central portion of the bell with the straight end portions thereof.

699,862. FINGER-GUARD FOR BRAKE-BEAMS. CHARLES E. WILLIAMS, Jr., Chicago, Ill., assignor to Chicago Railway Equipment Company, Chicago, Ill., a Corporation of Illinois. Filed Feb. 12, 1901. Serial No. 88,794. (No model.)

Claim.—1. The combination with a brake-beam, of a guard-finger passing through an opening in the flange of the beam; and means for securing the inner end of the guard-finger to the web of the beam; substantially as described.

2. The combination with a brake-beam, of a guard-finger connected thereto at two points, said guard-finger between said points being formed with a hook portion for the attachment of a safety-chain; substantially as described.

3. The combination with a brake-beam, and a guard-finger whose inner end is formed as a hook for the attachment of a safety-chain; substantially as described.

4. The combination with a brake-beam, of a guard-finger having a reduced inner end, said guard-finger having a shouldered engagement with the flange of the beam, and the said reduced portion being provided with a shoulder 8, and means for securing the guard-finger in position by clamping the web of the beam against said shoulder 8; substantially as described.

5. The combination with a brake-beam, of a guard-finger having a bent inner end forming a hook for the attachment of a safety-chain and a shouldered engagement with the brake-beam at a point beyond said bent portion; substantially as described.

6. The combination with a brake-beam having an elongated opening, of a guard-finger rotatably mounted in the flange of the beam and capable of rotation whereby one end thereof will pass through said elongated opening, and means for securing said guard-finger in its final position; substantially as described.

7. The combination with a brake-beam having an opening in its flange, of a guard-finger rotatably mounted therein, the inner end of said guard-finger being bent, said bent end being received in an opening in the web of the beam upon the rotation of said guard-finger, and means for securing said bent end in said opening; substantially as described.

8. The herein-described guard-finger whose inner end is reduced in diameter and bent to form a hook for the attachment of a safety-chain; substantially as described.

9. The herein-described guard-finger whose inner end is reduced in diameter, tapered and bent to form a hook; substantially as described.

10. The herein-described guard-finger whose inner end is reduced in diameter, tapered and bent to form a hook, the extreme end of said hook portion being shouldered and provided with attaching means; substantially as described.

699,863. DEMAGNETIZER. GUYAV BENTON, Milwaukee, Wis. Filed Mar. 21, 1901. Serial No. 88,692. (No model.)

Claim.—1. A demagnetizer comprising a hollow-core electromagnet, a pair of conductor-combs mounted on a slide to have the teeth of one in intervals between the teeth of the other, circuit-terminal brushes in contact with continuous free portions of the combs, and other brushes arranged in electric connection with said magnet to have contact with the comb-teeth.

2. A demagnetizer comprising a hollow-core electromagnet, a pair

of conductor-combs mounted on a slide to have the teeth of one in intervals between the teeth of the other, circuit-terminal brushes in contact with continuous face portions of the combs, resistance in circuit with said brushes, and other brushes arranged in electrical connection with said magnet to have contact with the comb-teeth.

3. A demagnetizer comprising an insulating-base, an insulating-slide on the base, a pair of conductor-combs mounted on the slide to have the teeth of one in the intervals between teeth of the other, an insulating-block flat on said base and provided with a guide-groove for the slide, a hollow-core electromagnet and binding-posts on the blocks, brushes in circuit with the binding-posts and arranged on said block to extend through a slot in same against continuous face portions of the combs, and other brushes arranged on the adjacent block in electric connection with said magnet to extend through the block-slot and contact with the comb-teeth.

699,864. COAL-MINING MACHINE. JOHN DUNSON and WILLIAM E. LAWREN, Myrtle, Tenn. Filed Nov. 12, 1900. Serial No. 30,317. (No model.)

Claim.—In a coal-mining machine, the combination with the frame having a rotating shaft with slide-movable, beveled gear-wheels arranged at suitable distances apart thereon, girths arranged one above the other, a slotted slide mounted on the upper girth, a vertical worm-shaft having its upper end journaled in the upper girth and passing through the slot of the slide, a bevel-gear on said upper end of the worm-shaft, a cog gear-wheel on the lower end thereof meshing with crank-wheel journaled on a cross-bar of the frame, a cutter-bar drive-shaft, a cutter-bar with teeth mounted on the crank-pins of the said crank-wheel, whereby a longitudinal and vertical movement is imparted to said cutter-bar, substantially as specified.

699,865. GOVERNOR. EUGENE COMANOR, Erie, Pa. Filed Apr. 20, 1901. Serial No. 62,000. (No model.)

Claim.—1. In a governor for pumps, the combination with a centrifugal element; a driving means for actuating said element; mechanism

arranged to operate upon said centrifugal element and means actuated by the pumped fluid for operating said mechanism to vary its force independently of the speed of the driving means.

2. In a governor for pumps, the combination of a centrifugal element; a centrifugal element arranged to act in opposition to said centrifugal element; mechanism for varying the strength of said centrifugal element independently of any variation of strength in the centrifugal element and means actuated by the pumped fluid for operating said mechanism.

3. In a governor for pumps, the combination of a centrifugal element; mechanism for automatically varying the speed of the centrifugal element and means actuated by the pumped fluid for operating said mechanism.

4. In a governor, the combination of a centrifugal element; a centrifugal element arranged to act in opposition to said centrifugal element; means acting independently of said centrifugal element for automatically varying the strength of said centrifugal element and mechanism for actuating said means.

5. In a governor for pumps, the combination of a centrifugal element; a centrifugal element arranged to act in opposition to said centrifugal element; means acting independently of said centrifugal element for automatically varying the speed of said centrifugal element and mechanism for actuating said means.

6. In a governor for pumps, the combination of a centrifugal element; a centrifugal element acting in opposition to said centrifugal element; means acting independently of the centrifugal element for automatically varying the speed of the centrifugal element and mechanism actuated by the pumped fluid for operating said means.

7. In a pump-governor, the combination of a centrifugal element; a speed-changing device for said centrifugal element; a pressure device arranged to be actuated by the pumped fluid; a counter-pressure device operating upon said pressure device with a varying pressure; and a connection between said pressure device and the speed-changing device.

8. In a governor for pumps, the combination with the centrifugal element; a speed-changing device for driving said element; a pressure device arranged to be actuated by the pressure of pumped fluid; and a connection between said pressure device and speed-changing device.

9. In a governor for pumps, the combination of a centrifugal element; a speed-changing device; a pressure device arranged to be operated by the pumped fluid; a spring arranged against said pressure device; and a connection between said pressure device and the speed-changing device.

10. In a governor for pumps, the combination of a centrifugal element; a speed-changing device; a pressure device arranged to be operated by the pumped fluid; a spring arranged against said pressure device; means for varying the tension of the spring; and a connection between said pressure device and the speed-changing device.

11. In a governor for pumps, the combination of a centrifugal element; a speed-changing device arranged in the driving mechanism of said element; a pressure device arranged to be actuated by the pressure of pumped fluid; a counter-pressure device arranged against said pressure device; means for varying the force of said counter-pressure; and a connection between said pressure device and speed-changing device.

12. In a governor for pumps, the combination of a centrifugal element; a disk for driving said centrifugal element; an opposing disk connected with the driving element of the governor; a friction-roller between said disks; means for varying the relative position of said roller on said disks for varying the speed; a pressure device arranged to be actuated by the pumped fluid; and a connection between said pressure device and said friction-roller whereby said roller is actuated relatively to the axes of said disks by said pressure device.

13. In a governor for pumps, the combination of the centrifugal element; the friction-disk, D', for driving said element; the driving-disk, J'; the friction between said disks; the rolls, m m, and shaft H; a bearing for said rolls carried by said friction; means for shifting said roller in said friction; and means for holding said roller in engagement with said disk.

14. In a governor for pumps, the combination of the centrifugal element; the friction-disk, D', for driving said element; the driving-disk, J'; the friction between said disks; the rolls, m m; the shaft, H; a bearing for said rolls carried by said friction; means for shifting said bearing in said friction; means for holding said rollers in engagement with said disks; a pressure device arranged to be operated by the pumped fluid of a pump controlled by said governor; and a connection between said pressure device and the bearing carrying said rolls, whereby said rolls are shifted by a movement of the pressure device.

15. In a governor, the combination of the disk, J'; the casing, I; the disk, D'; the rolls, m m; the sleeve, L; the shaft, H connecting the rolls journaled in the sleeve; the transmission, K; means for carrying pressure on the transmission to hold the rolls in contact with the disk; and means for

adjusting the position of the sleeve, I, in the transmission for varying the relative speed of the disk.

16. In a governor, the combination of the centrifugal element; the centrifugal element arranged to oppose said centrifugal element; the disk, D', for driving the centrifugal element; the casing, I, arranged in the disk, D'; the flange, T, secured to the casing, I; the bearing, J, on said flange, T; the shaft, J', arranged in said bearing; the pulley, J'', fixed on said shaft; the disk, J''', fixed on said shaft, mid disk, J'' and D', having the bevel described the rollers, m, n; the shaft, M, connecting said rollers; the sleeve, L, on which said shaft is journaled; the tension, K; a spring for exerting pressure on said tension to hold the roller in contact with said disk; the pressure-cylinder, R', having a connection, r; the piston, R, in said cylinder; the cap, r', on said cylinder; the spring, Q, tensioned against the piston and said cap; the stem, P', extending from said piston; the lever, P, secured to said stem; the weight, P'', on said lever; and the yoke, O, connecting said lever with the sleeve, L.

699,866. SHEET-DELIVERY APPARATUS FOR PRINTING-MACHINES. CHARLES F. OUTRELL, Westbury, N. Y., assignor to G. R. Ottrell & Son Company, New York, N. Y., a Corporation of New Jersey. Filed Nov. 21, 1901. Serial No. 22,694. (No model.)

Claim.—1. In a printing-machine, the combination with an impression-cylinder and a delivery-table, of a carriage between said cylinder and table, an endless carrier in said carriage, delivery-pulleys between said cylinder and carriage, means for giving said carriage a to-and-fro movement between said cylinder and table, and means for giving said carrier two forward movements within said carriage, one while the latter is stationary at the end of its movement toward the cylinder and the other while it is moving backward toward the cylinder, substantially as herein described.

2. In a printing-machine, the combination with an impression-cylinder and a delivery-table, of a carriage between said cylinder and table, delivery-pulleys between said cylinder and carriage, an endless carrier in said carriage, means for giving said carriage both a forward movement toward said table while said carrier remains in fixed position within it, and a return movement, and means for giving said carrier two forward movements within said carriage, one while the latter is stationary at the end of said return movement and the other during said return movement, substantially as herein described.

3. The combination with the impression-cylinder and a delivery-table arranged in front thereof in a printing-machine, of a carriage and stationary guides therefor and means for giving the said carriage a to-and-fro movement between said cylinder and table, a carrier comprising endless tapes and carrying shafts and pulleys therefor in said carriage, driving-wheels and means for transmitting constant rotary motion thereto from the cylinder, and wheels on one of said shafts for transmitting motion to said carrier from the said driving-wheels for the purpose of conveying printed sheets into said carriage, substantially as herein described.

4. In a printing-machine, the combination with the impression-cylinder and delivery-pulleys in front thereof, of a delivery-table arranged in front of said delivery-pulleys, a carriage and stationary guides therefor and means for giving said carriage a forward movement from said delivery-pulleys toward the table and a return movement and for holding it stationary between said movements, a carrier comprising endless tapes and carrying shafts and pulleys therefor in said carriage, means for giving said carrier a forward movement in the carriage while the latter is so held stationary, a stationary toothed rack and a pinion on and having a ratchet-and-pawl engagement with one of said shafts and gearing with said rack for giving said carrier a movement toward the table for discharging the sheets from the carriage during said return movement, substantially as herein described.

5. The combination with the impression-cylinder and a delivery-table arranged in front thereof in a printing-machine, of a carriage and stationary guides therefor and means for giving the said carriage a to-and-fro movement between said cylinder and table, a carrier comprising endless tapes and carrying shafts and pulleys therefor in said carriage, driving-wheels and means for transmitting constant rotary motion thereto from the cylinder, wheels on one of said shafts for transmitting motion to said carrier from the said driving-wheels for the purpose of conveying printed sheets into said carriage while it is stationary at the end of its movement toward the cylinder, a stationary toothed rack, and a pinion on and having a ratchet-and-pawl engagement with the other of said shafts and gearing with said rack for the purpose of giving said carrier a movement toward the table for discharging sheets from the carriage while the latter returns toward the cylinder, substantially as herein described.

699,867. SHEET-DELIVERY MECHANISM FOR PRINTING-MACHINES. CHARLES F. OUTRELL, Westbury, N. Y., assignor to G. R. Ottrell & Son Company, New York, N. Y., and Westbury, Conn., a Corporation of New Jersey. Filed Nov. 27, 1901. Serial No. 22,571. (No model.)

Claim.—1. In a printing-machine, the combination of a rotary impression-cylinder, a fly delivery-frame and mechanism for operating the same, a chain delivery-carrier consisting of chains and attached grippers, tapes common to said fly-frame and to said carrier for receiving the printed sheets from said cylinder and presenting them either to said fly-frame or said carrier and means for covering the said mechanism with the fly-frame in an inoperative position between the tapes and below the operative portions thereof, substantially as and for the purpose herein described.

2. In a printing-machine, the combination of a rotary impression-cylinder, a fly delivery-frame and a rack-shaft for said frame, a chain delivery-carrier consisting of chains and attached grippers, tapes common to said fly-frame and to said carrier for receiving sheets from the cylinder

and presenting them either to said fly-frame or to said carrier, a toothed sector on said rack-shaft, a rack-bar engaging with said sector, a rotary cam and operating mechanism between said cam and said rack-bar, and a detent applied to said mechanism for holding it out of operative relation to said cam with the fly-frame stationary below the operative portions of the tapes, substantially as herein described.

699,868. MEANS FOR CARRYING BOTTLES. HARTWILL M. A. HANSEN, Milwaukee, Wis. Filed Feb. 10, 1902. Serial No. 22,628. (No model.)

Claim.—1. In means for carrying bottles, the combination of a sterilizing-tank, a track leading therefrom, a device for supporting the opposite end of the track, said supporting device being located convenient to the point where the bottles are labeled or tin-filled, a bottle-carrying table consisting of a series of separate sections having horizontal platforms and supporting-wheels adapted to run on the track, the horizontal platforms adapted to fit end to end when the sections are together, and means for stopping the forward motion of the table at the end of its travel in one direction on the track, whereby the table-sections, after they have traveled to the limit of their extent in one direction, form a continuous table.

2. In means for carrying bottles, the combination of a sterilizing-tank, a track leading therefrom at a downward incline for a desired distance, a device for supporting the opposite end of the track, said supporting device being located convenient to the point where the bottles are labeled or tin-filled, the portion of the track supported by said supporting device being on a horizontal or substantially horizontal plane, a bottle-carrying table consisting of a series of separate sections having horizontal platforms and supporting-wheels adapted to run on the track, said platforms adapted to fit end to end when the sections are together, and means for stopping the forward travel of the table at the completion of its travel in one direction on the track, whereby the table-sections, after they have traveled the limit of their travel in one direction, form a continuous table.

3. In means for carrying bottles, the combination of a sectional track, a frame for supporting the terminal track-section and located convenient to the point where the bottles are labeled or tin-filled, a sterilizing-tank to which the initial track-section is connected, a bottle-carrying table consisting of a series of separate sections having horizontal platforms and supporting-wheels adapted to run on the track, the horizontal platforms adapted to fit end to end when the table-sections are together, and means for stopping the travel of the forward table-section at the end of the terminal track-section, whereby the several table-sections, after they have traveled the limit of their travel in one direction, form a continuous table.

4. In means for carrying bottles, the combination of a sectional track, a frame for supporting the terminal track-section and located convenient to the point where the bottles are labeled or tin-filled, a sterilizing-tank to which the initial track-section is connected, a supporting means carried at the ends of the rails of one track-section and adapted to removably support the adjacent ends of the rails of the other track-section, a bottle-carrying table consisting of a series of separate sections having horizontal platforms and supporting-wheels adapted to run on the track, the horizontal platforms adapted to fit end to end when the table-sections are together, and means for stopping the forward table-section at the end of the terminal track-section, whereby the several table-sections, after they have traveled the limit of their travel in one direction, form a continuous table.

5. In means for carrying bottles, the combination of a sectional track, a frame for supporting the terminal track-section and located convenient to the point where the bottles are labeled or tin-filled, a sterilizing-tank to which the initial track-section is connected, a U-shaped cocket connected to the ends of the rails of one track-section and adapted to receive and removably support the adjacent ends of the rails of the other track-section, a bottle-carrying table consisting of a series of separate sections having horizontal platforms and supporting-wheels adapted to run on the track, the horizontal platforms adapted to fit end to end when the table-sections are together, and means for stopping the travel of the forward table-section at the end of the terminal track-section, whereby the several table-sections, after they have completed their travel in one direction, form a continuous table.

6. In means for carrying bottles, the combination of a sectional track, a frame for supporting the terminal track-section and located convenient to the point where the bottles are labeled or tin-filled, a sterilizing-tank, means for adjustably connecting the initial track-section to said sterilizing-

tank, a bottle-carrying table consisting of a series of separate sections having horizontal platforms and supporting-wheels adapted to run on the track, the horizontal platforms adapted to fit end to end when the table-sections are together, and means for stopping the travel of the forward table-section at the end of the terminal track-section, whereby the several table-sections, after they have completed their travel in one direction, form a continuous table.

7. In means for carrying bottles, the combination of a sectional track, the rails of the initial track-section having a plurality of notches on their under edges, a frame for supporting the rails of the terminal track-section, and located convenient to the point where the bottles are labeled or tin-filled, a sterilizing-tank, the upper edge of one of the sides thereof adapted to be engaged by any of the corresponding notches of the rails of the initial track-section, a bottle-carrying table consisting of a series of separate sections having horizontal platforms and supporting-wheels adapted to run on the track, the horizontal platforms adapted to fit end to end when the table-sections are together, and means for stopping the travel of the forward table-section at the end of the terminal rail-section, whereby the several table-sections, after they have completed their travel in one direction, form a continuous table.

699,869. SHOE-LACING. HATTIS W. REILLY, New York, N. Y. Filed July 27, 1901. Serial No. 22,595. (No model.)

Claim.—1. A shoe-lacing separated throughout a portion of its length into a plurality of longitudinal parts or sections, substantially as set forth.

2. A shoe-lacing comprising a central non-separable body portion included between portions separated into a plurality of longitudinal sections or parts, substantially as set forth.

3. A shoe-lacing comprising a central non-separable body portion, portions on the opposite sides of the non-separable body portion separated into a plurality of longitudinal parts or sections and tips for pulling the several sections or parts, substantially as set forth.

699,870. GAS-RETORT. CHARLES W. REILLY, New York, N. Y. Original application filed May 15, 1901, Serial No. 22,528. Divided and this application filed Aug. 21, 1901. Serial No. 22,751. (No model.)

Claim.—1. The combination with an upright gas-retort having upwardly-directed channels in its inner face and an external furnace for heating said retort, of means for introducing steam or air directly into the lower part of said retort without its entering the furnace, substantially as and for the purpose herein described.

2. The combination with an upright gas-retort having upwardly-directed channels in its interior, of a retort-bottom in which is a chamber for air or steam, means for supplying air or steam to said chamber, and a valve for opening communication between said chamber and the interior of the retort, substantially as and for the purpose herein described.

3. The combination with an upright gas-retort having upwardly-directed channels in its interior, of a retort-bottom in which is a chamber for air or steam, means for supplying air or steam to said chamber, a grate supported on and some distance above said bottom for the support of the charge in the retort, and a valve for opening communication between said chamber and the space within the retort below said grate all substantially as herein described.

for shifting the gear-wheel to throw its clutch-pins into connection with said complementary clutch-pins; a cam having neutral and active portions for actuating said lever; and means for operating said cam.

33. The combination, with a driving-shaft, of a friction-clip having a hub splined to said driving-shaft; a quill loosely mounted on the driving-shaft; a driven shaft connected with the quill; a second friction-clip loose upon the quill; a gear fixed to said friction-clip; a grooved sleeve splined to the quill; keys carried by the sleeve; expansion-rings locked to the sleeve by said keys; pivoted levers for expanding said expansion-rings; a shifter-sleeve; wedge-blocks secured to said shifter-sleeve and traveling in grooves of the sleeve splined to the quill; an angle-lever; a slide having a cam for actuating said angle-lever; a gear mounted upon the hub of the friction-clip splined to the driving-shaft; clutch-pins carried by said gear; clutch-pins upon the friction-clip; an angle-lever for reciprocating said gear along the hub; a cam carried by the slide for actuating said angle-lever; means for actuating the slide; and means for connecting the gear on the hub of the friction-clip splined to the driving-shaft with the gear of the friction-clip loose upon the quill.

34. The combination, with a driving-shaft, of a quill splined on said shaft; a driven shaft controlled by the quill; a clutch member carried by the driving-shaft; means for connecting said clutch member to the quill; and means for reversing the motion of the quill, said means including a shiftable element adapted to be engaged with said clutch member.

35. The combination, with a shaft, of a device connected to rotate with said shaft; a clutch part carried by said device; a shiftable element loosely mounted with relation to said device, and having a groove to receive said clutch part; a complementary clutch part carried by said shiftable element; a moved shaft; and means for connecting said device with said moved shaft.

36. In mechanism of the class described, the combination, with a driving-shaft, of a clutch member connected to said driving-shaft; a quill loosely mounted on the driving-shaft; a driven shaft actuated by the quill; means for locking said clutch member to the quill; reversing mechanism, including a second clutch member; and means for locking said second clutch member to the quill.

37. The combination, with a shaft, of means for driving said shaft in one direction; a clutch device carried by a member of said means; a shiftable element having a groove to receive the clutch device; a clutch device carried by said shiftable element; and shaft-reversing mechanism connected with said shiftable member.

699,878. SPEED-CONTROLLING AND REVERSING MECHANISM. MOSES C. JOHNSON, Hartford, Conn. Filed Jan. 13, 1908. Serial No. 88,181. (No model.)

Claim.—1. The combination, with a shaft, of a quill loose on the shaft; means for rotating the quill; a clutch element splined upon and connected to the quill; gearing carried by said clutch element; a complementary clutch element; a carrier for said complementary clutch element, said carrier being rigid with the shaft; a gear on the shaft adjacent to said carrier; means for actuating the complementary clutch element in lock with said clutch element splined upon the quill to the carrier, and means for connecting the gearing of the clutch element splined upon the quill with the gear upon the shaft.

2. The combination, with a shaft, of a quill loose on said shaft; means for rotating said quill; a clutch element splined upon and connected to the quill; a carrier rigid with the shaft; a complementary clutch element mounted on the carrier; means for actuating said complementary clutch element; and shaft-reversing mechanism controlled by the quill.

3. The combination, with a shaft, of a quill loosely mounted on said shaft; a device secured to said quill; a gear carried by said device; a carrier secured to the shaft; mechanism for clatching said device to the

carrier; means for actuating said clatching mechanism; a counter-shaft; a gear loosely mounted on said counter-shaft; means for connecting said gear in the counter-shaft; a gear fixedly mounted on the counter-shaft; and mechanism connecting said gear with the shaft.

4. The combination, with a driven shaft, of a quill loosely mounted on said shaft; a device having a hub secured to said quill; a counter-shaft; gearing loosely mounted on said counter-shaft; a gear fixed to the counter-shaft; a gear carried by the driven shaft and in mesh with said fixed gear; gearing in mesh with the loose gear of the counter-shaft, said gearing being carried by the device having a hub secured to the quill; an idler for connecting one of the gears carried by the hub with one of the gears of the counter-shaft; and means for connecting the gear in mesh with the idler with said counter-shaft.

5. The combination, with a driven shaft, of a quill loosely mounted on said shaft; means for rotating the quill; a device having gears carried by the quill; a counter-shaft; gears loosely mounted on said counter-shaft; a gear fixed to said counter-shaft; an idler between one of the gears of the device on the quill and one of the loosely-mounted gears on the counter-shaft; a gear carried by the driven shaft and in mesh with the fixed gear of the counter-shaft; means for connecting said gear to the driven shaft; devices for alternately clatching the loosely-mounted gear to the counter-shaft; a cam; connections from said cam for actuating said devices; and means for actuating the cam.

6. The combination, with a driven shaft, of a quill mounted on said shaft; a sleeve secured to the quill; gearing carried by the sleeve; a counter-shaft; a gear loosely mounted on said counter-shaft and in engagement with an element of the gearing carried by the sleeve; another gear loosely mounted on said counter-shaft; an idler connecting said gear with another member of the gearing carried by the sleeve; means for alternately clatching the loosely-mounted gear to the counter-shaft; a cam-shaft; a cam carried by said cam-shaft; lever-and-link connections between said cam and the clutch-actuating devices of the counter-shaft; a fixed gear carried by the counter-shaft; a gear in engagement with said fixed gear; means for securing said gear to the driven shaft; and means for actuating the cam-shaft.

7. The combination, with a shiftable element, of means for actuating said element; a link connected to said actuating means; a rocker movably connected to and supporting said link; a cam; a device carried by the link and actuated by said cam; and means for actuating said cam.

8. The combination, with a shiftable element, of a yoke for actuating said element; an arm projecting from said yoke; a link articulated to the arm; a rocker pivoted to the link; a cam; a device carried by the link and bearing against the cam; and means for actuating said cam.

9. The combination, with a driven shaft, of mechanism for actuating said shaft at one speed in a forward direction; mechanism for actuating said shaft at a different speed in a forward direction; mechanism for reversing the rotation of said shaft; a cam; links carrying devices acted upon by said cam; means for connecting one of said links with the reversing mechanism; means for connecting the other link with the mechanism for driving the shaft in a forward direction; and rockers to which said links are pivoted.

10. The combination, with a driven shaft, of a counter-shaft; gearing connecting said driven shaft and counter-shaft; means for locking an element of said gearing to the counter-shaft when it is desired to rotate the driven shaft at a slow speed in a forward direction; means for connecting another element of said gearing to the counter-shaft when it is desired to reverse the rotation of said driven shaft; means for rotating the driven shaft at a fast speed in a forward direction; a cam; and mechanism for connecting said cam with the means for imparting rotary movement to said shaft.

11. The combination, with a driven shaft, of a carrier secured to said driven shaft; a friction-clip; a continuously-driven quill to which said clip is connected; an expansion-ring between the friction-clip and carrier; a counter-shaft; gearing between said friction-clip and the counter-shaft; a fixed gear carried by the counter-shaft; a gear carried by the driven shaft and in engagement with said fixed gear of the counter-shaft; means for connecting the gear carried by the driven shaft to said driven shaft; means for alternately clatching certain gear of the counter-shaft to said shaft; means for actuating the expansion-ring in the friction-clip; a cam; and connections from the cam for actuating all of said means.

12. The combination, with a driven shaft, of a quill loose on said shaft; means for rotating the quill; a sleeve secured to said quill; a counter-shaft; a pair of gears loosely mounted on said counter-shaft; a pair of gears carried by the sleeve on the quill, one of which is in engagement with one of the loosely-mounted gears of the counter-shaft; an idler in engagement with the other loosely-mounted gear of the counter-shaft and with the other gear of the pair carried by the quill; gearing for connecting the counter and driven shafts; devices for clatching the loosely-mounted gears to said counter-shaft; and a cam for actuating said devices.

13. The combination, with a driven shaft, of a quill loose on said

shaft; means for rotating the quill; a hub or carrier secured to the driven shaft; means for connecting said quill to the hub or carrier; a counter-shaft; a gear fixed to said counter-shaft; a gear on the driven shaft; means for connecting said gear to the driven shaft; gears loosely mounted on the counter-shaft; means for clatching either of said gears to the counter-shaft; a cam and connections for actuating said means; gears carried by the quill; and a gear for connecting one of said gears carried by the quill with one of the gears of the counter-shaft.

14. The combination, with a driven shaft, of a quill loose on said driven shaft; means for rotating said quill; a hub or carrier secured to the driven shaft; means for connecting the quill to said hub or carrier to rotate said driven shaft at a fast speed in a forward direction; means for connecting the quill with the driven shaft to rotate the driven shaft at a different speed in a forward direction; and means controlled by the quill for reversing the movement of the driven shaft.

15. The combination, with a driven shaft, of a quill loose on said shaft; means for rotating the quill; a pair of gears controlled by the quill; means for connecting the quill to the driven shaft to turn said shaft at a fast speed in a forward direction; a counter-shaft; a pair of gears loosely mounted on said counter-shaft, one of said gears being in mesh with one of the gears controlled by the quill, a gear connecting the other loose gear of the counter-shaft with the other gear controlled by the quill; clutch connections for clatching said loosely-mounted gear to the counter-shaft; means for actuating said connections; a gear fixed to the counter-shaft; and means connecting said gear with the driven shaft.

16. The combination, with a driven shaft, of a quill; means for rotating said quill; a sleeve rotating with the quill; means for connecting said sleeve to the driven shaft to drive the same at a certain speed; means for connecting said quill with the driven shaft to rotate the same at a different speed; means for connecting said quill with the driven shaft to reverse the motion thereof; a cam; and devices actuated by said cam for affecting the connections set forth.

17. The combination, with a driven shaft, of a quill loosely mounted on said shaft; a hub or sleeve secured to the quill; a sleeve mounted for reciprocatory movement on said hub or sleeve; clutch devices for connecting the sleeve with the hub; gearing carried by the reciprocatory sleeve; a counter-shaft; a gear loosely mounted upon the counter-shaft and in engagement with an element of the gearing of the sleeve; a gear fixed to the counter-shaft; a gear in engagement with said fixed gear and carried by the driven shaft; and means for connecting said last-named gear to said driven shaft.

18. The combination, with a driven shaft, of a quill loosely mounted on said shaft; a hub secured to the quill; a reciprocatory sleeve carried by the hub; means for reciprocating said sleeve; clutch devices connecting said sleeve and hub; a counter-shaft; gearing for connecting the sleeve with said counter-shaft; a fixed gear carried by the counter-shaft; a gear in engagement with said fixed gear, and carried by the driven shaft; and means for connecting said gear to the driven shaft.

19. The combination, with a shaft, of a quill loosely mounted on said shaft; means for rotating said quill; a hub splined to the quill; a reciprocatory sleeve mounted upon the hub; means for clatching said reciprocatory sleeve to the hub; a gear carried by the sleeve; a counter-shaft; a gear loosely mounted on said counter-shaft; means for clatching said gear to the counter-shaft; a fixed gear carried by the counter-shaft; a gear loosely mounted on the driven shaft; and means for clatching said gear to the driven shaft.

20. The combination, with a driven-shaft, of a quill loose on said shaft; means for rotating the quill; a hub splined to said quill; a friction-clip carried by the hub; an expansion-ring located within said friction-clip; a carrier secured to the driven shaft; means for locking the expansion-ring to the friction-clip; a sleeve mounted on the hub of the friction-clip; means for reciprocating said sleeve; clutch devices carried by the sleeve; a counter-shaft; gearing carried by the sleeve; a counter-shaft; gearing carried by said counter-shaft; means for locking said gearing to the counter-shaft; and gearing connecting the counter-shaft with the driven shaft.

21. The combination, with a shaft, of a quill loosely mounted on said shaft; means for rotating the quill; a friction-clip having a hub secured to the quill; clutch devices carried by said friction-clip; a sleeve mounted on the hub; clutch devices carried by said sleeve; gearing also carried by the sleeve; means for reciprocating the sleeve; a counter-shaft; gears loosely mounted on said counter-shaft; devices for locking said gears to the counter-shaft; a gear intermediate one of said counter-shaft gears and one of the gears carried by the hub; a fixed gear carried by the counter-shaft; a gear in engagement with said fixed gear and loosely mounted on the driven shaft; and means for connecting said gear to said driven shaft.

22. The combination, with a shaft, of a quill loosely mounted on said shaft; a friction-clip having a hub splined to said quill; means for rotating the quill and thereby the friction-clip; a clutch device within the

friction-clip, means for actuating said clutch device; a sleeve mounted on the hub; means for reciprocating said sleeve; clutch devices carried by the sleeve and adapted to engage with the clutch devices of the clip; a pair of gears carried by the sleeve; a counter-shaft; a pair of gears loosely mounted on said counter-shaft; clutch mechanisms for locking said loosely-mounted gears to the counter-shaft; a gear intermediate one of the loosely-mounted gears of the counter-shaft and one of the sleeve-gears; a fixed gear carried by the counter-shaft; a gear in engagement with said fixed gear and loosely mounted on the driven shaft; clutch devices carried by said gear; a carrier secured to the driven shaft; clutch devices movable on said carrier and adapted to engage with the clutch devices of the gear; and means for actuating the clutch devices of the carrier.

23. The combination, with a shaft, of a quill loosely mounted on said shaft; means for rotating the quill; a hub splined to the quill; a friction-clip carried by the hub; means for connecting said friction-clip to the driven shaft; a sleeve movable on the hub; clutch devices between said sleeve and hub; gears carried by the sleeve; a counter-shaft; gears loosely mounted on the counter-shaft; clutch devices for locking one of said gears to said counter-shaft; clutch devices for locking another of said gears to said counter-shaft; a gear intermediate one of said loosely-mounted gears and one of the gears of the movable sleeve and in engagement with each of said gears; a pinion fixed to the counter-shaft; a gear loosely mounted on the driven shaft; clutch devices carried by said gear; a carrier; clutch devices mounted on the carrier; and means for actuating said clutch devices to cause them to engage with the clutch devices of the gear.

24. The combination, with a shaft, of a quill loosely mounted on said shaft; means for rotating said quill; a friction-clip having a hub splined to the quill; a carrier secured to the shaft; an expansion-ring secured to said carrier; means for expanding said expansion-ring to lock the friction-clip to the carrier; a sleeve movable on the hub of the friction-clip; a gear carried by said sleeve; means for actuating the sleeve; clutch devices between the gear and friction-clip; a counter-shaft; a gear loosely mounted on said counter-shaft; means for connecting said gear to said counter-shaft; a pinion carried by the counter-shaft; a gear loose on the driven shaft and in engagement with said pinion; clutch devices carried by the gear; clutch devices mounted on the carrier; and means for actuating said clutch devices to cause them to engage with the clutch devices of the gear.

25. The combination, with a driven shaft, of a quill loose on said shaft; a hub splined to said quill; a sleeve movable on said hub; means for clatching the sleeve to the hub; a gear carried by the hub; a counter-shaft; a gear carried by the counter-shaft; means for clatching said gear to the counter-shaft; a gear intermediate the gear on the counter-shaft and the gear of the hub and in engagement with both of said gears; a pinion carried by the counter-shaft; a gear in engagement with said pinion; and means for clatching said gear to the driven shaft.

26. The combination, with a shaft, of a quill loose on said shaft; a hub splined to the quill; a sleeve movable on the hub; means for connecting the hub to the driven shaft; clutch devices intermediate the sleeve and hub; a counter-shaft; a gear loosely mounted on the counter-shaft and in engagement with the gear of the hub; means for reciprocating the sleeve on the hub to cause the clutch devices to engage; means for locking the gear on the counter-shaft to said counter-shaft after said clutch engagement has been made; a pinion on the counter-shaft; a gear loose on the driven shaft; and means for connecting said gear to the driven shaft.

27. The combination, with a driven shaft, of a quill loose on said shaft; means for rotating the quill; means for connecting the quill to the driven shaft, to drive the same at full speed forward; a sleeve; gears carried by the sleeve; means for reciprocating the sleeve; means for connecting the sleeve to the quill; a counter-shaft; a gear loose on the counter-shaft; means for connecting said gear to the counter-shaft; a gear fixed to the counter-shaft; a gear loose on the driven shaft; clutch-pins carried by said gear; a carrier secured to the driven shaft; clutch-pins movable on the carrier; and means for actuating said clutch-pins to cause them to engage the clutch-pins of the gear and rotate the driven shaft at a slow forward speed.

28. The combination, with a driven shaft, of a quill loose on said shaft; means for rotating the quill; a hub splined to the quill; means for connecting said hub to the driven shaft to rotate the same in one direction; a sleeve movable on the hub; clutch devices between the hub and sleeve; and means for rotating the driven shaft in a reverse direction, said sleeve constituting a part of the reversing means.

29. The combination, with a shaft, of mechanism for rotating said shaft; means for connecting said mechanism to the shaft; a cam-shaft; a cam; means for actuating the cam; lever-and-link mechanism actuated by the cam and controlling the shaft-rotating mechanism; a device carried by each of the link parts of said lever-and-link mechanism; and means for latching said device in fixed relation to the cam.

30. The combination, with a shaft, of means for rotating said shaft at a slow forward speed; means for rotating said shaft at a fast forward speed; means for reversing the rotation of the shaft; a movable sleeve

constituting a part of the slow forward and reversing mechanism; means for connecting said sleeve to the shaft; and a cam having active and non-active portions for actuating said sleeve and said mechanism.

31. The combination, with a driven shaft, of a quill loose on said shaft; means for rotating the quill; a hub splined to the quill; a friction-cup carried by the hub; means for connecting said friction-cup to the driven shaft; clutch-pins carried by the friction-cup; a sleeve movable on the hub of the friction-cup; gears carried by the sleeve; a counter-shaft; a pair of gears loosely mounted on said counter-shaft; clutch devices for locking said gears to the counter-shaft; means for actuating each of said clutch devices; a gear in engagement with one of the gears of the sleeve and with one of the loosely-mounted gears of the counter-shaft; a fixed gear on the counter-shaft; a loose gear on the driven shaft and in engagement with said fixed gear; clutch-pins carried by said loose gear; a carrier splined to the driven shaft; clutch-pins movable in ways of the carrier; means for actuating said clutch-pins to cause them to engage the clutch-pins of said loose gear; a cam; and means intermediate said cam for shifting the clutch-pins-actuating mechanism.

32. The combination, with a shaft, of a quill splined on said shaft; a hub rotating with the quill; a clutch element carried by the hub; a clutch element carried by the shaft; means for actuating one of said clutch elements to connect the shaft and hub; a counter-shaft; and gearing controlled by the hub for changing the speed of the shaft on which the quill is splined.

33. The combination, with a shaft, of a quill splined to said shaft; a hub carried by and rotating with the quill; a clutch element carried by the hub; a clutch element carried by the shaft; means for actuating the clutch element carried by the shaft to connect the shaft and hub; means for applying power to the quill; a counter-shaft; reversing mechanism of which the hub carried by the quill constitutes a part; and means for connecting said reversing mechanism with the shaft.

34. The combination, with a shaft, of a hub or carrier secured to said shaft; a gear loose on the shaft; clutch devices carried by the gear; clutch devices movable on the hub or carrier; means for actuating said clutch devices of the carrier; and means for rotating the gear and, through the hub or carrier to which it is splined, the shaft.

35. The combination, with a shaft, of a hub or carrier splined to the shaft; a power-transmitting element loose on the shaft; clutch-pins mounted in guides of the hub or carrier; means for reciprocating said clutch-pins; clutch-pins carried by the power-transmitting element; and means for actuating said element and, through the hub or carrier, the shaft.

36. The combination, with a shaft, of a hub or carrier splined to said shaft; said hub or carrier having open slots; means for rotating the hub or carrier and thereby the shaft at full speed in a forward direction; a gear loosely mounted on the shaft adjacent to said hub or carrier; clutch-pins carried by the gear; means for reciprocating the clutch-pins of the hub or carrier to cause them to engage the clutch-pins of the gear; and means for rotating said gear when such engagement is made, and thereby the hub or carrier, at a slow, forward speed.

37. The combination, with a shaft, of a hub or carrier having longitudinal guideways splined to said shaft; means for rotating the hub or carrier, and thereby the shaft, at a fast speed forward; clutch-pins; means for reciprocating the clutch-pins in the guideways of said hub or carrier; a gear loosely mounted on the shaft adjacent to said hub or carrier; clutch-pins carried by the gear; means for reciprocating the clutch-pins of the counter-shaft and in mesh with the gear carrying the clutch-pins; means for locking said loose gear to the counter-shaft; and means for rotating the counter-shaft and thereby causing the shaft to which the hub or carrier is splined to rotate at a slow speed in a forward direction.

38. The combination, with a shaft, of a hub or carrier splined to said shaft; a quill loose on the shaft; means for rotating the quill; a hub splined to the quill; means for clamping said hub to the hub or carrier; a gear loose on the shaft and located adjacent to one end of said hub or carrier; means for clamping the hub or carrier to said gear; means for releasing the clutch devices connecting the hub or carrier and the hub splined to the quill; and means for rotating the gear adjacent to one end of said hub or carrier.

39. The combination, with a driven shaft, of a hub or carrier splined to said shaft; a gear loosely mounted on the shaft adjacent to one end of said hub or carrier; means for clamping the hub or carrier to said gear; a counter-shaft; a gear loosely mounted on said counter-shaft; means for clamping said gear to the counter-shaft; means for rotating said gear when thus locked to the counter-shaft; and a gear carried by the counter-shaft and in mesh with the gear loosely mounted on the driven shaft.

40. The combination, with a driven shaft, of a hub or carrier splined to said shaft and having guideways; clutch-pins mounted in the guideways; a shifting ring mounted upon the hub or carrier and connected with said clutch-pins; means for actuating said shifting ring; a gear loose on the driven shaft and located adjacent to one end of said hub or carrier;

clutch-pins carried by said gear and adapted to engage with the complementary pins of the hub or carrier; a counter-shaft; a gear carried by said counter-shaft and in mesh with the gear loose on the driven shaft; and means for rotating said counter-shaft.

41. The combination, with a driven shaft, of a hub or carrier splined to said shaft and having longitudinal guideways; clutch-pins mounted in said guideways; a shifting ring; studs projecting from the shifting ring and in engagement with the clutch-pins; a cam; means controlled by said cam for actuating the shifting ring; a gear loosely mounted on the driven shaft adjacent to one end of the hub or carrier; clutch-pins carried by the gear; a counter-shaft; a gear carried by said counter-shaft and in mesh with the gear loose on the driven shaft; and means for actuating the counter-shaft.

42. The combination, with a driven shaft, of a hub or carrier splined to said shaft and having open slots; clutch-pins mounted in said slots; a shifting ring; studs projecting from said shifting ring passing through the slots of the hub or carrier and engaging said clutch-pins; a revoluble cam; means controlled by said cam for actuating the shifting ring; a gear loose on the driven shaft; clutch-pins carried by the gear and adapted to engage the complementary pins of the hub or carrier; a counter-shaft; a gear carried by said counter-shaft, and in engagement with the gear loose on the driven shaft; and means for rotating the counter-shaft.

43. The combination, with a driven shaft, of a hub or carrier splined to said shaft and having longitudinal guideways; a shifting ring mounted on the hub or carrier; clutch-pins mounted in the guideways of said hub or carrier; studs projecting from the shifting ring and in engagement with said clutch-pins; a revoluble cam; lever-and-link mechanism controlled by said cam for actuating the shifting ring; a power-transmitting element loose on the driven shaft adjacent to one end of the hub or carrier; clutch-pins carried by said power-transmitting element; and means for rotating said power-transmitting element.

44. The combination, with a driven shaft, of a hub or carrier secured to said shaft; an expansion-ring attached to the hub or carrier; a friction-cup; means for actuating said expansion-ring and thereby locking the cup and hub or carrier together; means for rotating the friction-cup; a power-transmitting element located adjacent to said hub or carrier; means for clamping said power-transmitting element to the hub or carrier; and means for rotating the power-transmitting element.

45. The combination, with a driven shaft, of a hub or carrier secured to said shaft; means for driving said hub or carrier and thereby the driven shaft at a fast speed in a forward direction; a power-transmitting element loosely mounted on the driven shaft adjacent to said hub or carrier; means for clamping said power-transmitting element to the hub or carrier; means for rotating said power-transmitting element at a slow speed in a forward direction; and means for reversing the rotation of said power-transmitting element, and, through the hub or carrier clamped thereto, the driven shaft.

46. The combination, with a driven shaft, of a hub or carrier splined to said shaft; an expansion-ring secured to said hub or carrier; a shifting ring mounted on the hub or carrier; means controlled by the shifting ring for actuating said expansion-ring; a friction-cup surrounding said expansion-ring and having a hub; a quill to which the hub of the friction-cup is splined; means for rotating the quill; clutch devices movable on the hub or carrier; means connecting the shifting ring with said clutch devices; a power-transmitting element loose on the driven shaft adjacent to the hub or carrier; clutch devices carried by said power-transmitting element and adapted to engage the clutch devices of the hub or carrier; a counter-shaft; means for rotating said counter-shaft in different directions; and means carried by the counter-shaft for actuating the power-transmitting element loose on the driven shaft.

47. The combination, with a driven shaft, of a hub or carrier secured to said shaft; a friction-cup; means for clamping said friction-cup to the hub or carrier; means for rotating the friction-cup, and thereby the hub or carrier and driven shaft, at full speed in a forward direction; devices for actuating said means; a power-transmitting element loose on the driven shaft adjacent to the hub or carrier; means for clamping said power-transmitting element to the hub or carrier; and means for rotating said power-transmitting element in different directions.

48. The combination, with a shaft, of a hub or carrier secured to said shaft; means for rotating the hub or carrier and thereby the shaft; a cam; means for actuating said cam; a link carrying a pin in engagement with the cam; a rocker movably connected to the link; and devices controlled by the link and connecting the means for rotating the hub or carrier to said hub or carrier.

49. The combination, with a shaft, of a hub or carrier secured to said shaft; means for rotating the hub or carrier; a grooved cam; a link having a pin fitted in the groove of said cam; a rocker to which the link is pivoted; and devices controlled by said link for clamping the means for rotating the hub or carrier to said hub or carrier.

50. The combination, with a shaft, of means for rotating said shaft;

a grooved cam; means for actuating the cam; a link having a pin located in the groove of said cam; a rocker connected to said link; and means controlled by the link for actuating the shaft-rotating means.

51. The combination, with a shaft, of means for rotating said shaft; a grooved cam; means for actuating the cam; a link having a pin; a rocker to which one end of the link is pivoted; a yoke having an arm to which the other end of the link is connected; and devices controlled by the yoke for connecting the shaft-rotating means to said shaft.

52. The combination, with a shaft, of means for rotating said shaft in forward and reverse directions; a cam; means for actuating the cam; links having devices in engagement with the cam; rockers movably connected to the links; and means controlled by said links for connecting the mechanisms for rotating the shaft to said shaft.

53. The combination, with a shaft, and with means for rotating said shaft, of a grooved cam having active and non-active portions secured to the shaft; a link having a pin fitted in the groove of said cam; a rocker to which one end of said link is articulated; a movably-mounted yoke having an arm to which the opposite end of said link is pivoted; a driven shaft; a hub or carrier secured to said driven shaft; shaft-rotating mechanism; and means controlled by the yoke for clamping said shaft-rotating mechanism to the hub or carrier.

54. The combination, with a driven shaft, of mechanism for rotating said shaft; a hub or carrier secured to said shaft; a shifting ring mounted on said hub or carrier; means controlled by the shifting ring for clamping one of the shaft-rotating mechanisms to said hub or carrier; means for actuating the shifting ring; a grooved cam; a link pivoted to said shifting ring, and having a pin fitted in the groove of the cam; a rocker to which said link is articulated; and means controlled by the link for throwing another of the shaft-rotating mechanisms into action.

55. The combination, with a driven shaft, of a hub or carrier splined to said shaft; a quill loosely mounted on the shaft; a friction-cup having a hub splined to said quill; means for rotating the quill; means for coupling the friction-cup to the hub or carrier; a sleeve movably mounted on the hub of the friction-cup; means for actuating the sleeve; gears carried by the sleeve; clutch devices between one of the gears and the friction-cup; a counter-shaft; and means controlled by said counter-shaft for actuating the driven shaft in different directions.

56. The combination, with a driven shaft, of a hub or carrier splined to said shaft; a quill loose on the shaft; means for rotating the quill; a device having a hub splined to said quill; means for clamping said device to the hub or carrier; a sleeve mounted on the hub; clutch mechanism carried by the sleeve; complementary clutch mechanism carried by the friction-cup; means for reciprocating the sleeve; a counter-shaft; and gearing connecting the counter-shaft with the hub or carrier splined to the driven shaft.

57. The combination with a driven shaft, of a hub or carrier splined to said shaft; a friction-cup; clutch-pins carried by said friction-cup; means for coupling said cup to the hub or carrier; means for rotating the friction-cup; a gear having clutch-pins adapted to engage with the clutch-pins of said friction-cup; means for throwing said clutch-pins into engagement with the complementary clutch-pins; a counter-shaft; gearing carried by the counter-shaft; means for clamping said gearing to the counter-shaft; a gear loose on the driven shaft; a gear carried by the counter-shaft and in engagement with said loose gear; and means for clamping said loose gear to the hub or carrier.

58. The combination, with a shaft, of means for rotating said shaft; mechanism for reversing the rotation of said shaft; a cam; means for actuating said cam; a link; a device carried by the link and in engagement with the cam; a rocker to which the link is pivoted; and means connecting said link with a part of the shaft-reversing mechanism.

59. The combination, with a shaft, of means for rotating said shaft; mechanism for reversing the rotation of the shaft; a clutch constituting a part of the shaft-reversing mechanism; clutch-actuating mechanism; a grooved cam; means for actuating said cam; a link having a pin; devices connecting the link with the clutch-actuating mechanism; and a rocker for controlling the movement of the link upon its pin.

60. The combination, with a shaft, and with means for actuating the same, of a grooved cam having active and non-active portions secured to said shaft; a link; a pin carried by the link, said pin entering the cam-groove; a rocker to which the link is pivoted; and a shiftable element to which said link is connected.

61. The combination, with a grooved cam, of means for actuating said cam; a link; a pin carried by the link and entering the groove of the cam; a rocker connected to the link; and a shiftable element also connected to the link.

62. Speed controlling and reversing mechanism comprising the following instrumentalities in combination: a shaft; means for rotating the shaft at full speed forward; means for rotating said shaft at slow speed forward; means for reversing the rotation of said shaft; a cam having a series of active and passive portions; a link and connections operated by the cam for throwing the full-speed shaft-actuating mechanism into and

out of action; devices actuated by said link for throwing the slow-speed, shaft-actuating mechanism into and out of action; a second link; and devices operated by said second link for throwing the shaft-reversing mechanism into and out of action.

63. Speed controlling and reversing mechanism comprising the following instrumentalities in combination: a shaft; means for rotating said shaft at slow speed in a forward direction; means for rotating said shaft at fast speed in a forward direction; means for reversing the rotation of said shaft; a grooved cam having a series of active and passive portions; a link carrying a pin entering the cam-groove; connections from the link for throwing the mechanism for actuating the shaft at a slow speed forward into and out of action; connections from the link for throwing the mechanism for actuating the shaft at fast speed in a forward direction into and out of action; a rocker pivoted to the link; a second link having a pin entering the cam-groove; a rocker articulated to said second link; and means actuated by the second link for throwing the shaft-reversing mechanism into and out of action.

699,874. CLUTCH. MOSES C. JOHNSON, Hartford, Conn. Filed Feb. 4, 1902. Serial No. 92,164. (No model.)

Claim.—1. The combination, with a shaft, of a clutch; means for actuating said clutch; connected devices movably mounted on said means; and means for adjusting said devices to cause them to move toward each other.

2. The combination, with a shaft, of a friction-cup; an expansion-ring; a pair of levers movably mounted on said ring; a device for actuating said levers to cause them to lock the expansion-ring to the friction-cup; connected blocks carried by said levers; and means for adjusting said blocks toward each other.

3. The combination, with a shaft, of a friction-cup; an expansion-ring located within the friction-cup; a pair of levers; mechanism for actuating said levers to expand the ring; and a device for connecting said levers and causing them to move simultaneously.

4. The combination, with a shaft, of a friction-cup; an expansion-ring fitted within said cup; means controlled by the cup, when said ring is expanded, for actuating the shaft; a pair of levers movably mounted on the expansion-ring, said levers having pockets with inclined bottom walls; blocks having inclined surfaces fitted in said pockets; means for adjusting said blocks simultaneously transversely of the levers; and means for directly connecting the blocks so that when one is actuated the other will move therewith.

5. The combination, with a shaft, of a member loose on said shaft; an expansion-ring; a member secured to the shaft and to which the expansion-ring is connected; a pair of levers carried by the expansion-ring, the levers having pockets with inclined bottom walls; blocks with inclined surfaces fitted in the pockets of said levers; means for adjusting one of said blocks; means for connecting one block with the other block, so that the blocks will move toward each other when one of them is adjusted; and means for actuating the levers.

6. The combination, with a shaft, of a member loose on said shaft, said member having a friction-surface; an expansion-ring; a pair of pivoted levers carried by said expansion-ring; blocks fitted within pockets of said levers; means for adjusting one of said blocks transversely of the lever in which it is supported; and means for connecting said block with the other block, whereby both blocks may be simultaneously moved toward each other when one of them is adjusted.

7. The combination, with a shaft, of a friction member; an expansion-ring located within said friction member; a pair of levers pivoted on said expansion-ring, each of said levers having a pocket; blocks fitted within said levers, means for adjusting one of said blocks; and means for connecting one block with the other block, so that when actuated by the adjusting means the blocks will move in unison and will be forced toward each other.

8. The combination, with a shaft, of a friction member; an expansion-ring located within the friction member; levers pivoted on said expansion-ring; a toothed connection between the levers; and means for actuating the levers.

9. The combination, with a shaft, of a friction member; means for connecting said friction member with the shaft, said means involving an expansion-ring; levers pivoted to said expansion-ring, each lever having a socket with an inclined wall; a block having an inclined wall fitted in

one of said sockets, said block having a dot; a tooth carried by the block; a screw, a flange of which is fitted in said dot; and a block having an inclined wall fitted in the socket of the other lever, said block having a recess for the reception of the tooth of the other block.

10. The combination, with a shaft, of a friction member; means for connecting said friction member with the shaft, said means involving an expansion-ring; levers pivoted to said expansion-ring, each lever having a pocket with an inclined bottom wall; blocks movably mounted in the pockets of the levers; means for adjusting one of said blocks; and a toothed connection between the blocks.

11. The combination, with a shaft, of a friction member; means including an expansion-ring for connecting said member with the shaft; levers pivoted to the expansion-ring; a toothed connection between said levers, whereby they are caused to rock in unison; and means for actuating the levers to cause them to expand the expansion-ring and lock it in said friction member.

12. The combination, with a shaft, of a friction member; means for connecting said friction member with the shaft; said means including an expansion-ring having sockets in its two ends; levers having horns fitted in said sockets; a toothed connection between said levers; a wedge-block for actuating the levers to expand the expansion-ring and lock it in the friction member; and means for actuating said wedge-block.

13. The combination, with a shaft, of a friction member; an expansion-ring adapted to be connected to said friction member; means for connecting said expansion-ring to the shaft; levers pivoted to the expansion-ring; each lever having a pocket; blocks fitted in the pockets of the levers; means for connecting the blocks; means for adjusting one of said blocks; and means for actuating the levers to cause them to lock the expansion-ring to the friction member.

14. The combination, with a shaft, of a friction member; an expansion-ring; levers pivoted to the expansion-ring; engaging surfaces on the levers; a toothed connection between said surfaces; and means for actuating the pivoted levers to cause them to lock the expansion-ring to the friction member.

15. The combination, with a shaft, of a friction member; an expansion-ring; lever mechanism for expanding the expansion-ring; a device for connecting the elements of the lever mechanism so that they will move in unison; means for adjusting said device; and means for actuating said lever mechanism.

16. The combination, with a shaft, of a friction member; an expansion-ring; levers pivoted on the ends of the expansion-ring; said levers having straight and inclined engaging surfaces; a toothed connection between said engaging surfaces; and means for actuating the levers.

17. The combination, with a shaft, of a friction-cup; an expansion-ring; means for connecting said ring with the shaft; levers pivoted to the expansion-ring, and each having a pocket with an inclined bottom wall; blocks seated in said pockets and having inclined portions fitting against said bottom walls, one of said blocks having a dot; a screw having a projection engaging said dot; a connection between the blocks; and means for actuating the levers.

18. The combination, with an expansion-ring, of means for supporting said ring; levers having enlargements fitted in sockets of the ring; means for actuating the levers; and means engaging with said enlargements for preventing disengagement of the levers from the ring.

19. The combination, with an expansion-ring having sockets in its two ends, of a support for said ring; levers having grooved enlargements fitted in said sockets; means for actuating the levers; and pins passing through the ring and entering the grooves in the enlargements of said levers.

699,875. REVELOT AND BLANK THEREFOR. AMUSEMENT. Liverpool, England. Filed Nov. 26, 1900. Serial No. 97,260. (No model.)

Claim.—1. An improved article of manufacture, consisting of a block provided with a series of tabs at one edge, and a series of cut-away portions approximately rectangular in shape in the other edge in the same relative plane as the tab portions, strips of gum or other adhesive substance extending transversely of said block from points between said tabs on one edge to points in the same relative plane between the said

cut-away portions of the opposite edge, said gum strips being of uniform width throughout their length, the lower portion of said block being designed to be folded upon and directly secured to the remainder thereof, by means of said gum strips, for forming a series of envelopes each having a rectangular including space, the said block having a single line of perforations extending through the central longitudinal line of each of said strips of gum, whereby the envelopes may easily be torn apart without interfering with the adhesion of the gum strips, thereby facilitating the passage of the envelope through a type-writer in sheet or strip form before separation, substantially as described.

2. An improved article of manufacture, consisting of a single blank having one edge provided with a series of flaps or extensions, and the opposite edge provided with a series of cut-away portions, corresponding in number and in line with the said flaps, a strip of gum or other adhesive material extending from a point midway between each flap to a point midway between each cut-away portion of uniform width throughout its length, a single line of perforations extending along through the central line of each of said gummed portions, the construction and arrangement being such that when one portion of the blank is folded upon the other, and caused to adhere directly thereto substantially as described, a series of envelopes is formed having rectangular including spaces, each envelope of the series being easily capable of separation by tearing along the line of perforations, whereby the passage of the envelope through a type-writer in sheet or strip form is facilitated.

699,876. GOLF-BALL. BRADLEY KIMBALL, Boston, Mass., assignor to the Kimball Manufacturing Company, a Corporation of New Jersey. Filed Apr. 1, 1902. Serial No. 101,997. (No model.)

Claim.—1. A playing-ball having a cloth cover, said ball comprising a springy core and a colloid casing with which said cover is incorporated.

2. A playing-ball having a cloth cover, said ball comprising a sphere of gutta-percha, and a colloid casing upon said sphere, the cloth being incorporated with said casing.

3. A playing-ball having a cloth cover, said ball comprising a springy core, a sphere of gutta-percha including said core, and a casing of colloid upon said sphere, the cloth being incorporated with said casing.

4. A playing-ball having a cloth cover, said ball comprising a shell of colloid upon which said cover is applied; the cloth being incorporated with the colloid.

5. A playing-ball having a sectional cloth cover, said ball comprising a sphere of plastic material and a casing consisting of welded segments of colloid each of which has incorporated therewith a section of said cloth cover.

699,877. TRACTION-TRUCK. ALFRED ELLIS, Danversville, Mo. Filed Jan. 25, 1902. Serial No. 91,344. (No model.)

Claim.—1. In a traction-truck, the combination with a series of grooved rollers mounted to revolve in close proximity to each other, of

an endless track on said rollers consisting of a series of strips having tongues at their centers, links connecting said tongues, and said tongues and links so shaped as to form a continuous smooth bearing for the grooved periphery of the rollers.

2. In a traction-truck, the combination with a series of grooved rollers mounted to revolve between parallel bars, of an endless track consisting of a series of beveled strips, central tongues on the strips bifurcated at each end, links pivotally connecting the tongues on adjacent strips, and the outer or upper edges of said links and tongues in alignment forming a smooth track on which the grooved rollers run.

699,878. RIBBON-LOOM. REYNOLD KREHLMAN, Philadelphia, Pa. Filed July 31, 1901. Serial No. 70,380. (No model.)

Claim.—1. In combination with a ribbon-loom, a shaft adapted to extend transversely of the loom-beam, bearings secured to and depending from the loom-beam in which the shaft is journaled, two pulleys journaled loosely upon said shaft, two cords, one end of one cord being attached to one of the pulleys, and one end of the other cord attached to the other pulley, pulleys journaled in the loom-beam, one of the cords adapted to pass around one of the pulleys and be attached to the rack, the other cord adapted to pass around the other pulley and also be attached to the rack, said last-named pulleys so placed that when the cords are pulled alternately the rack will be reciprocated, means for rocking the transverse shaft a predetermined part of one revolution backward and forward, clamping mechanism adapted to alternately connect first one end and then the other of the pulleys journaled upon the transverse shaft to said shaft each time the shaft is rocked in one given direction, means whereby the pulley in clutch with the shaft will rotate the other pulley in the opposite direction at the same rate of speed so that the cord connected to one of the pulleys will be wound upon the same, and the cord connected to the other pulley will be unwound from the same, substantially as described and for the purpose specified.

2. In an operation of the character described, a shaft adapted to extend transversely across the loom-beam, bearings secured to and depending from said loom-beam, in which said shaft is journaled, two pulleys journaled loosely upon said shaft, two cords, one of which is attached to one of the pulleys and the other attached to the other pulley, two pulleys journaled in the loom-beam, one of the cords adapted to pass over one of the pulleys and be secured to the rack, the other cord adapted to pass over the other pulley and also be secured to the rack, said pulleys so arranged in the loom-beam that when the cords are alternately pulled the rack will be reciprocated, a hand-wheel adapted to be journaled upon a suitable bearing depending from the loom-beam, two bands or straps secured to the hand-wheel and wound upon the same in opposite directions; said bands or straps adapted to be alternately pulled so as to rock said hand-wheel a predetermined part of one revolution backward and forward, a crank-arm journaled loosely upon the transverse shaft, an arm secured to the transverse shaft, a curved slot formed in the crank-arm concentric to the transverse shaft, a screw or bolt adapted to pass through said

slot and be secured to the arm which is secured to the transverse shaft, a connection between the hand-wheel and the crank-arm whereby the hand-wheel is rocked with the crank-arm, clamping mechanism whereby the pulleys journaled upon the transverse shaft are alternately connected to said shaft so as to rock therewith, means whereby the pulley which is in clutch with the shaft will cause the other pulley to rotate in the opposite direction the same distance and at the same rate of speed, whereby the cord connected to one pulley will be wound upon the same, and the cord connected to the other pulley will be unwound from the same, said pulleys adapted to be so placed relative to one another, and the crank-arm so placed relative to the transverse shaft as to cause the shuttle to travel any distance backward and forward, provided said distance is less than that represented by the circumference of the pulleys, and the hand-wheel adapted to be rocked a distance backward and forward to correspond with the adjustment of the pulleys and the crank-arm, substantially as and for the purpose specified.

3. In a device of the character described, means for increasing the speed of the shuttle midway of its travel and decreasing the speed toward each end of its stroke, consisting of a bracket having a vertical slot formed therein, which bracket supports the steel upon which the hand-wheel is journaled, a shoulder formed upon said steel bearing against the lower surface of the bracket, a nut threaded upon the outer end of the steel for the purpose of holding said steel within the slot at any position it is placed, a crank-arm having a longitudinal slot formed therein, a block secured to the hand-wheel and adapted to slide in said slot, said hand-wheel adapted to be adjusted within the vertical slot so that its end may be on a line with the transverse shaft upon which the crank-arm is journaled, or may be made concentric thereto by lowering said hand-wheel within the slot, substantially as described and for the purpose specified.

4. In a device of the character described, clamping mechanism consisting of a dog pivoted to each of the pulleys journaled upon the transverse shaft, a spring adapted to hold the outer edge of the dogs normally beyond the periphery of the pulleys, a notch formed in the dogs, pawls secured to the transverse shaft and adapted to rock therewith, springs pivoted to a hanger depending from the loom, springs adapted to normally hold said springs in contact with the periphery of the pulleys and push one of the dogs forward so that the notch will be in the path of travel of the pawls and engage said notch to carry the pulley with it in its revolution, said pulleys adapted to be so placed relative to one another that both the dogs will never be in contact with the spring-cams at the same time, but the pulleys will be so rotated that the opposite dog to the one engaged by the pawl will be brought in contact with the cam at the limit of its movement and forced in the path of travel of the pawl so as to be engaged by the same upon the next movement of the pawl, means for locking the dogs in their reared position when engaged by the pawl, and means for releasing said locking mechanism when the pawl has made about one-half of its retrograde movement, substantially as and for the purpose set forth.

699,879. RIBBON-LOOM. REYNOLD KREHLMAN, Philadelphia, Pa. Filed Aug. 26, 1901. Serial No. 72,728. (No model.)

Claim.—1. In combination with a ribbon-loom of the character described, bearings secured to the back loom, clutch-pulleys journaled loosely transversely of the loom and adapted to be supported by said bearings, said clutch-pulleys arranged in pairs, one pair for each series of shuttles, two cords for each pair of pulleys, one end of one cord being attached to one pulley of the pair, one end of the other cord attached to the other pulley of the pair, the pulleys journaled in bearings on the loom-beam, one of the cords of each pair of clutch-pulleys adapted to pass from said clutch-pulleys in one direction and pass around the idle pulleys and be attached to the rack, the other cord of the same pair of clutch-pulleys adapted to pass in the opposite direction around another idle pulley and be attached to the rack, said idle pulleys so placed that when the cords are pulled alternately the rack will be reciprocated, means for rocking the transverse shaft upon which the clutch-pulleys are journaled a predetermined part of one revolution backward and forward, clamping mechanism adapted to alternately connect first one end and then the other of the clutch-pulleys of each pair to their shafts each time the shafts are rocked in one given direction, means whereby the pulley in clutch with the shaft will rotate the other pulley of the pair in the opposite direction at the same rate of speed so that the cord connected to one of the pulleys of the pair will be wound upon the same, and the cord connected to the other pulley of the pair will be unwound from the same, means whereby the clamping mechanism is thrown in and out of engagement with different pairs of clutch-pulleys automatically by the raising and lowering of the front loom, substantially as described and for the purpose set forth.

2. In an operation of the character described, one or more shafts adapted to extend transversely across the loom-beam, bearings secured to the back loom in which said shaft or shafts are journaled, clutch-pulleys

journalled loosely upon said shaft or shafts, said clutch-pulleys arranged in pairs, one pair for each series of clutches carried by the latter, two cords for each pair of clutch-pulleys, one end of one of the cords of each pair attached to one of the clutch-pulleys of each pair, and one end of the other cord attached to the other pulley of the same pair, idle pulleys, two for each pair of clutch-pulleys, journalled in the front lath, one of the cords of each pair of clutch-pulleys adapted to pass around one pulley of each pair of idle pulleys, the other cord adapted to pass around the other idle pulley, and both cords adapted to be secured to one rack, said idle pulleys so arranged in the front lath that when the cords are alternately pulled the rack will be reciprocated, a hand-wheel journalled upon a suitable bearing extending from the back lath, two bands or straps secured to the hand-wheel and wound upon the racks in opposite directions, said bands or straps adapted to be alternately pulled so as to rack said hand-wheel a predetermined part of one revolution backward and forward, means for transmitting this backward-and-forward motion to the transverse shaft or shafts, clutching mechanism whereby one pair of pulleys journalled upon the transverse shaft is alternately connected to said shaft so as to be revolved therewith when the shaft or shafts are moved in one direction, means whereby the clutch-pulley which is in clutch with the shaft will cause the other pulley of the same pair to rotate in the opposite direction the same distance and at the same rate of speed, whereby the cord connected to one pulley will be wound upon the same, and the cord connected to the other pulley will be unwound from the same, the cords tied to the clutch-pulleys at such a point that when the front lath is raised certain distances the clutch-pulleys will be so revolved as to throw into engagement the clutching mechanism of a certain set of clutch-pulleys, and means for giving to the actuated clutch-pulleys a variation of speed, said means adapted to increase the speed at one-half of the revolution, and diminish the speed toward each end of the stroke, substantially as and for the purpose specified.

3. In combination with a device of the character described, clutching mechanism consisting of a dog pivoted to each of the clutch-pulleys, a spring adapted to hold the outer edge of the dogs normally beyond the periphery of the pulleys, a notch formed in the dogs, pawls secured to the transverse shaft or shafts and adapted to rest therewith, spring-cams pivoted to the back lath, springs adapted to normally hold said spring-cams in contact with the periphery of the pulleys, and said cams adapted to act so as to push the dogs inward so that the notch in the dog will fit in the path of travel of the pawls whenever said dogs are stepped in the proper position, means whereby only one pair of clutch-pulleys are adapted to work in conjunction with the clutch mechanism so as to reciprocate one of the racks at a time, a vertically-moving front-lath beam forming a part of the beam to which this device is attached, said pairs of clutch-pulleys adapted to be thrown in and out of contact with the clutching mechanism by the raising and lowering of the front lath, each pair of clutch-pulleys adapted to be so revolved relative to one another that both the dogs pivoted to said pulleys will never be in contact with the spring-

men at the same time, but the actuated clutch-pulleys will be so rotated that the dog of the opposite pulley of the pair engaged by the pawl will be brought in contact with its cam at the limit of its movement and travel in the path of the travel of the pawl so as to be engaged by the same upon the next movement of the pawl, means for locking the dogs in their raised position when engaged by the pawl, and means for releasing said locking mechanism when the pawl has made about one-half of its reverse movement, substantially as and for the purpose set forth.

699,880. CHECKROW PLANTER. WILLIAM LA FOLLETTE, Makaburg, Iowa. Filed Feb. 8, 1902. Serial No. 98,147. (No model.)

Claim.—1. A planter comprising a furrow-opener, a hopper above the furrow-opener and having a best leading to the latter, a valve mechanism for the hopper, a driving-wheel actuated by the furrow-opener, and connections between the driving-wheel and valve mechanism for operating the latter.

2. A planter comprising a furrow-opener, a hopper above the furrow-opener and having a best leading to the latter, a valve mechanism for the hopper, a driving-wheel actuated by the furrow-opener, and connections between the driving-wheel and valve mechanism for operating the latter, said connections being passed through the best.

3. A planter comprising a furrow-opener, a hopper above the furrow-opener and having a best leading thereto, a valve mechanism for the hopper including a dropping-link having a gear, a longitudinally-adjustable shaft having pinions fixed thereon and disposed at opposite sides of the gear for alternate engagement therewith and for simultaneous disengagement therefrom, a sprocket-wheel mounted slidably upon the shaft and splined thereto, a driving-wheel within the furrow-opener and projecting therebelow, a sprocket-wheel rotatable with the driving-wheel, and a chain connecting the wheels and passed through the best.

4. A planter comprising a furrow-opener, a hopper above the furrow-opener having a best leading to the latter, a driving-wheel within the furrow-opener and projecting therefrom, a dropping mechanism for the hopper and adjustable connections between the driving-wheel and dropping mechanism for reversely operating the dropping mechanism.

699,881. BABY-COACH OR GO-CART. AUGUSTUS R. LANFLORE, Philadelphia, Pa., assignor to Fannie Bloch and Harry Levi, copartners trading as the Philadelphia Baby Carriage Factory, Philadelphia, Pa. Filed Aug. 24, 1901. Serial No. 73,507. (No model.)

Claim.—1. In a baby-coach or go-cart, an axle, springs secured directly thereto, handle-ranches secured directly to said springs approximately at the juncture of said axle and springs, and a frame or body portion secured to said springs.

2. In a baby-coach or go-cart, an axle, a coupling-block secured to said axle, springs secured to said coupling-block, handle-ranches secured directly to said springs approximately at the juncture of said coupling-block and springs and braced upon said coupling-block, and a frame or body portion secured to said springs.

3. In a baby-coach or go-cart, an axle, a coupling-block mounted thereon and having a socket, springs mounted in the socket of said coupling-block,

means connecting said springs, coupling-block and axle, reaches connected directly with said springs and braced upon said coupling-block, and a frame or body portion secured to said springs.

4. The combination of a frame of a coach, springs for supporting the same, an axle and a coupling-block mounted upon said axle, said springs, coupling-block and axle being secured together, an overhanging arm at one end of said coupling-block, and a reach fastened under and engaged by said arm and provided with a dedicated end portion secured to said springs.

699,882. BABY-COACH OR GO-CART. AUGUSTUS R. LANFLORE and HARRY LEVI, Philadelphia, Pa., assignors to Fannie Bloch and Harry Levi, copartners trading as the Philadelphia Baby Carriage Factory, Philadelphia, Pa. Filed Aug. 24, 1901. Serial No. 73,508. (No model.)

Claim.—1. In a baby-coach or go-cart, a seat having a relatively tiltable back, locking device at the lower end portion thereof, an operating handle or finger-piece at the upper end portion thereof, and a connecting-piece extending in the plane of the back from said handle or finger-piece to said locking device.

2. In a baby-coach or go-cart, a seat having a relatively tiltable back, locking device at the lower end portion thereof, an operating handle or finger-piece at the upper end portion thereof, and a connecting-piece extending in the plane of the back between said handle or finger-piece and said locking device and entirely within the sides of said back.

3. In a baby-coach or go-cart, a seat having a relatively tiltable back, locking device at the lower end portion thereof, an operating handle or finger-piece and a spindle connected with said handle or finger-piece and said locking device, said spindle extending in the plane of said back.

4. In a baby-coach or go-cart, a seat having a relatively tiltable back, locking device at the lower end portion thereof, a rotatable spindle connected with said locking device for operating the same, said spindle extending upwardly in the plane of the back to the upper end portion thereof and provided at its upper end with an operating handle or finger-piece.

5. In a baby-coach or go-cart, a tiltable back, locking device at the lower end thereof, a spindle extending through one of the upright dovetails of the back and connected with said locking device for operating the same, and a handle or finger-piece at the upper end of said spindle.

699,883. BABY-COACH OR GO-CART. AUGUSTUS R. LANFLORE and HARRY LEVI, Philadelphia, Pa., assignors to Fannie Bloch and Harry Levi, copartners trading as the Philadelphia Baby Carriage Factory, Philadelphia, Pa. Filed Sept. 5, 1901. Serial No. 74,396. (No model.)

Claim.—1. The combination with a frame of a coach or go-cart, of a tiltable back and footpiece, locking means for holding said back and frame relatively immovable, and device for actuating said locking means to connect or disconnect the back and frame and by means of which said footpiece is engaged and moved with the back.

2. A coach or go-cart having a tiltable back and footpiece, locking means for said back, a movable member connected with said footpiece, and device for actuating said locking means, and by means of which said movable member is engaged and said footpiece moved with the back.

3. A coach or go-cart having a tiltable back and footpiece, locking means for said back, a movable member connected with said footpiece, a catch to hold said member, and device for actuating said locking means and for extending said catch and by means of which said movable member is engaged and the footpiece moved with the back.

4. A coach having a tiltable back and footpiece, a guide mounted upon a stationary part of the coach, a sliding member mounted upon said guide and connected with the footpiece, a catch carried by said sliding member and adapted to engage said guide, means for tilting the back and for holding it in adjusted position, said means being normally disconnected from and movable independently of said sliding member and provided with a member to engage said catch and sliding member for disengaging the catch and guide and for moving said sliding member upon the guide when the back is tilted.

5. A coach or go-cart having a tiltable back and footpiece, a movable member upon the frame of the go-cart, a link pivotally connected therewith at one end, a movable guide engaging the other end of said link, a second link pivoted to said first-mentioned link and to the footpiece, and means for tilting the back, adapted to engage said movable member to shift the same and tilt the footpiece.

6. A coach or go-cart having a tiltable back and footpiece, a guide secured to a stationary portion of the coach or go-cart, and provided with an opening near its upper end, a sliding member mounted upon said guide and pivotally connected with the footpiece, a spring-actuated catch carried by said sliding member and adapted to engage said opening in the guide, a shoulder upon said catch, means for tilting the back embodying a rotatable spindle having a lug adapted to engage said shoulder of the catch to move said catch against the action of the spring and to engage said sliding member to move the same upon the guide.

7. The combination with the frame of a coach or go-cart, of a swinging back provided with laterally-extending locking-pins at the lower end portion of the sides thereof, a spring for moving said pins outwardly, device carried by said back for moving said pins inwardly, said device extending to the upper end portion of the back and being provided therewith with a handle or finger-piece.

8. The combination with a frame of a coach, of a swinging back, a rotatable spindle extending through said back and substantially in the plane thereof, locking-pins mounted upon said back and connected with said spindle to be moved thereby, a series of sockets to receive the ends of said pins, and a spring for moving said pins toward said sockets.

9. The combination with a frame of a coach, of a pivoted back, a rotatable spindle extending through the dovetail thereof and above and below the same, pins mounted upon said back and geared to said spindle, arms at the sides of said frame provided with openings to receive said pins, and a spring for moving said pins outwardly and into said openings.

10. The combination with a frame of a coach, of a pivoted back, a rotatable spindle carried thereby and provided with a gear, pins mounted upon said back and having racks engaged by said gear, and arms upon said frame having openings adapted to engage said pins.

11. A coach having a tiltable back and footpiece, a guide mounted upon a stationary part of the coach, a sliding member mounted upon said guide and connected with the footpiece, interlocking means for said guide and sliding member adapted to interlock when the footpiece is elevated, means movable with the back for tilting the same and holding it in adjusted position, said means being provided with a member normally disconnected from and movable independently of said sliding member, and adapted to engage said interlocking means to unlock the same and allow the footpiece to descend, said member being also adapted to contact with and move the sliding member upon said guide to elevate the footpiece.

12. A coach having a tiltable back and footpiece, a guide mounted upon a stationary part of the coach, a sliding member mounted upon said guide and connected with the footpiece, a catch carried by said sliding member and adapted to engage said guide when the footpiece is elevated, means movable with said back for tilting the same and holding it in adjusted position, said means being provided with a member normally disconnected from and movable independently of said sliding member and

adapted to engage said catch to discharge the same from said guide to allow the footpiece to descend, said member being also adapted to contact with and move the sliding member upon said guide to elevate the footpiece.

699,884. BOTTLE-LABELING MACHINE. CHARLES LEVYMAN, Brooklyn, N. Y. Filed Feb. 23, 1900. Serial No. 6,985. (No model.)

Claim.—1. In a bottle-labeling machine, the combination with a bottle-carrier, of a label-applying mechanism cooperating therewith and means for adjusting the relative angular position of the carrier and label-applying mechanism.

2. In a bottle-labeling machine, the combination with a bottle-carrier, of two label-applying mechanisms cooperating therewith and means for adjusting the relative angular positions of the label-applying mechanisms.

3. In a bottle-labeling machine, the combination with a bottle-carrier, of two label-applying mechanisms cooperating therewith means for adjusting the relative angular position of the label-applying mechanisms, the driving-shafts of the two label-applying mechanisms being connected together.

4. In a bottle-labeling machine, the combination of a reciprocating label-holder, a printing device adapted to print on the top label in the holder, a reciprocating member and a system of levers between the reciprocating member and the printing device substantially as described.

699,885. GOLD-SEPARATOR. ROBERT C. LINTON, Napleton, N. D. Filed May 11, 1901. Serial No. 59,957. (No model.)

Claim.—1. A gold-separator having in combination a pipe curved downward near its middle, or between its ends forming a short and a long inclined arm, a vacuum-chamber at the upper side of the curve, opening into the pipe and having a petcock at its top, said chamber and curve of the pipe, being adapted to contain mercury; an inclined stirrer-shaft in the long arm of the pipe for driving and stirring the water-mixed gold-holding sand through the pipe, a stirrer at the outlet end of the short arm of the pipe for separating the mercury and gold from the sand or gravel before it leaves the machine, means for connecting and driving or operating said stirrer, and means for providing a current of water to pass through the pipe.

2. In a gold-separator and mounted in suitable framework the combination with a V-shaped pipe having a short outlet-arm and a long inclined inlet-arm of an inclined stirrer-shaft journaled to revolve axially in the long arm of the pipe, a vertical stirrer-shaft having a vertically-adjustable stirrer revolving in the mouth or outlet opening of the short pipe-arm, the horizontal operating-shaft 30, having the crank 23 and the pulley 24, the bevel-gears 18, 19 and 25 and 26 connecting the operating-shaft with both of the stirrer-shafts; said operating-shaft also having the long lay-

way 23, the pulley 24, and gear 25 having keys slidable in said keyway; a key secured in the gear 18 and the long keyway 11 in shaft 9; the said long pipe-arm having the slidable joint 31 with the cut-screw 28; the discharge-box 5 6, made in two overlapping sections, so as to be extendible when the joint 31 and the shaft 30 are extended.

699,886. WAXER FOR CUT-IRONS. BLAIR LEON, Newport, N. Y. Filed Mar. 18, 1901. Serial No. 61,457. (No model.)

Claim.—A waxing device for cut-irons, consisting of a shell provided with a handle at one end, a piece of wax under constant pressure in said shell, a helical spring interposed between the inner end of the wax and the shell, and a retaining-piece of textile fabric attached to the shell and extending over the open end of the same and the wax, substantially as set forth.

699,887. SOAP-PRIMER. JOHN B. HAMMAR, Toronto Junction, Canada, assignor of one-half to David Brown, Donaghmore, Ireland. Filed Dec. 11, 1901. Serial No. 55,473. (No model.)

Claim.—1. In a machine of the class described, the combination with the vertically-reciprocating disc, of a charging-table, a charger arranged to push the bars placed thereon into the disc, and a discharging-striker acting in the plane of the charger at an angle to the line of movement thereof adapted to discharge the pressed bar from the disc and throw the same laterally out of the path of the impressed bar which is to be advanced by the charger, substantially as set forth.

2. In a machine of the class described, the combination with a discharge having a mouth or opening at the top, of a vertically-reciprocating upper die adapted to force a cake to be pressed down into a die-box through said opening, the lower die reciprocating vertically within the die-box and arranged to return the stamped cake to the mouth of the box, a charging-table on a level with the mouth of the die-box, a charger arranged to push an unstamped cake along said table to the mouth of the die-box, a discharge-truck leading laterally from said mouth of the die-box, the discharging-striker arranged opposite said discharge-truck facing the same and acting across the mouth of the die-box to throw the pressed cake into the discharge-truck, and mechanism for automatically returning the several moving parts, as set forth.

3. In a machine of the class described, the combination with the vertically-reciprocating disc of a charging-table in front of said disc, a charger adapted to push between the disc a bar or cake placed on said charging-table, a discharging-striker acting at an angle to the charger in the same horizontal plane to discharge the pressed bar from the disc and throw the same laterally out of the path of the impressed bar which is to be advanced by the charger, and mechanism for actuating the striker, said mechanism being arranged to return the striker more quickly than the cake is advanced.

4. In a machine of the class described, the combination with the vertically-reciprocating disc, of a charging-table in front of said disc, a reciprocating charging-plunger arranged to slide to and fro on said table, and mechanism for actuating said plunger, a discharge-truck at right angles to the line of travel of the charging-plunger, a stop on the opposite side of the disc from the charging-plunger, a discharging-plunger arranged to slide to and fro in a path at right angles to the charging-plunger and facing the discharge-truck, mechanism for advancing the discharge-plunger, and a spring for quickly snapping back the said discharge-plunger after it has made its forward journey.

699,888. REVOLVING CHAIR. ARTHUR L. MARSHALL, NEWTON, Mass. Filed Jan. 6, 1902. Serial No. 58,884. (No model.)

Claim.—1. The combination of a beller consisting of an upper drum, an annular lower drum and tubes connecting said drums, a fire-chamber,

a combustion-chamber extending from the fire-chamber through the lower drum and up between the tubes toward the upper drum and an insulating casing or shell having its upper end closed and its lower end connected to the stack, substantially as set forth.

2. The combination of a beller consisting of upper and lower drums and vertical tubes connecting said drums, a metal shell including the drums and tubes, and a protecting-roof arranged above the beller and supported by the metal shell, substantially as set forth.

3. In a beller the combination of a beller consisting of an upper drum and an annular lower drum and tubes connecting said drums, a fire-chamber, an annular combustion-chamber extending from the fire-chamber through the lower drum and up between the tubes toward the upper drum and an insulating casing having its lower end connected to the stack and provided with a contracted throat above the point of connection with the stack, substantially as set forth.

4. The combination of a beller consisting of an upper drum, an annular lower drum and tubes connecting said drums, a fire-chamber located below the lower drum, an annular combustion-chamber extending from the fire-chamber up through the lower drum and between the tubes to a plane adjacent to the upper drum and an insulating case or shell having its lower end connected to the stack, substantially as set forth.

699,889. REVOLVING CHAIR. ARTHUR L. MARSHALL, NEWTON, Mass. Filed Jan. 6, 1902. Serial No. 58,884. (No model.)

Claim.—1. The combination of a hub, a spindle, a member supported by the hub and revoluble with respect to said hub, two of said parts having threaded engagement with each other, and means for locking the revoluble member to the spindle, under one adjustment of said means, to prevent rotation of the spindle in said revoluble member, and for unlatching said revoluble member from the spindle, and locking the same to the hub, under another adjustment of said means, one of said adjustments permitting of the spindle rotating without raising or lowering the same, and the other of said adjustments permitting of the vertical adjustment of the spindle.

2. The combination of a hub, a sleeve supported by the hub, a spindle within the sleeve, two of said parts having threaded engagement with each other, means for locking the sleeve to the hub, and means when the locking mechanism is disengaged from the hub for locking the sleeve and spindle together in order to prevent rotation of the spindle in the sleeve, one of said adjustments permitting of the spindle rotating without raising or lowering the same, and the other of said adjustments permitting of the vertical adjustment of the spindle.

3. The combination of a hub, a sleeve supported by the hub, a spindle within the sleeve, two of said parts having threaded engagement with each other and means for locking the sleeve to the hub under one adjustment of said means, and under another adjustment of said means to disengage said means from the hub and cause the same to engage and lock the sleeve and spindle together in order to prevent rotation of the spindle in the sleeve, one of said adjustments permitting of the spindle rotating without raising or lowering the same, and the other of said adjustments permitting of the vertical adjustment of the spindle.

4. The combination of a hub, a sleeve supported by the hub, a longitudinally-recessed spindle within the sleeve, two of said parts having threaded engagement with each other and locking means engaging the sleeve and adapted under one adjustment to also engage the recess of the spindle and thereby lock the sleeve and spindle together, in order to prevent rotation of the spindle in the sleeve, and under another adjustment to be disengaged from the recess of the spindle and engage the hub, and thereby lock the sleeve to said hub, one of said adjustments permitting of the spindle rotating without raising or lowering the same, and the other of said adjustments permitting of the vertical adjustment of the spindle.

5. In a revolving chair, the combination of a hub having a threaded

here, an exteriorly-threaded and longitudinally-slotted sleeve, the threads thereof engaging the threaded bore of the hub, a longitudinally-recessed spindle depending from the chair-seat and revoluble in the sleeve, a loose member, a part carried by the loose member, and having one portion thereof, when said part is under one adjustment, adapted to extend into the slot of the sleeve, and, when under another adjustment, to have another portion thereof adapted to extend through the slot of the sleeve and into the recess of the spindle, and means adapted, when the portion of said part which engages only the slot of the sleeve, is in engagement with said slot, to lock the loose member and the said part carried thereby against turning.

6. In a revolving chair, the combination of a hub having a threaded bore and provided on its top with a plurality of steps, an exteriorly-threaded and longitudinally-slotted sleeve, the threads thereof engaging the threaded bore of the hub, a longitudinally-recessed spindle depending from the chair-seat and revoluble in the sleeve, a loose member, a part carried by the loose member, and having one portion thereof, when said part is under one adjustment, adapted to extend into the slot of the sleeve, and having another portion thereof, when said part is under another adjustment, adapted to extend through the slot of the sleeve and engage the recess of the spindle, and means adapted to engage any of the series of steps, when the portion of said part which engages only the slot of the sleeve is in engagement with said slot, to thereby lock the loose member and the said part carried thereby against rotation.

7. In a revolving chair, the combination of a hub having a threaded bore, and also provided with a step, an exteriorly-threaded and longitudinally-slotted sleeve, the threads thereof engaging the threaded bore of the hub, a longitudinally-recessed spindle depending from the chair-seat and revoluble in the sleeve, a loose member, a part carried by the loose member, and having one portion, when said part is under one adjustment, adapted to extend into the slot of the sleeve, and having another portion, when said part is under another adjustment, adapted to extend through the slot of the sleeve and engage the recess of the spindle, said part also provided with a dog adapted to engage the step of the hub, when the portion of the said part which engages only the slot is in engagement with said slot, to thereby hold the loose member and the said part which it carries against rotation.

8. In a revolving chair, the combination of a hub having a threaded bore and also provided with a step, an exteriorly-threaded and longitudinally-slotted sleeve, the threads thereof engaging the threaded bore of the hub, a longitudinally-recessed spindle depending from the chair-seat and revoluble in the sleeve, a loose member on the top of the hub and surrounding the threaded sleeve, a lever pivoted to the loose member, and having its short arm, when the lever is turned in one direction, adapted to extend into the slot of the sleeve, and having its long arm provided with a depending dog adapted to engage the step on the hub when the short arm of the lever is engaging the slot of the sleeve, the said long arm of the lever when the lever is turned in the opposite direction adapted to be thrown into engagement with the slot of the sleeve and also in engagement with the recess of the spindle, when said recess is brought into registration with the slot.

9. The combination of a hub, a spindle, a sleeve supported by the hub, two of said parts having threaded engagement with each other, and means for locking the sleeve to the spindle under one adjustment of said means in order to prevent rotation of the spindle in the sleeve, and for locking said sleeve to the hub under another adjustment of said means, one of said adjustments permitting of the spindle rotating without raising or lowering the sleeve, and the other of said adjustments permitting of the vertical adjustment of the spindle.

10. The combination of a hub, a spindle, a sleeve supported by the hub, two of said parts having threaded engagement with each other, a loose member carried by the hub and revoluble thereon, and locking mechanism carried by the loose member and adapted for locking the sleeve to the spindle under one adjustment of the locking mechanism in order to prevent rotation of the spindle in the sleeve, and for locking said sleeve to the hub under another adjustment of said locking means, one of said adjustments permitting of the spindle rotating without raising or lowering the spindle, and the other of said adjustments permitting of the vertical adjustment of the spindle.

699,890. KNIFE-SHARPENER. ALFRED M. McLEMAN, Reno, Cal., Kans. Filed June 10, 1901. Serial No. 63,914. (No model.)

Claim.—1. A knife-sharpener, comprising a base portion, a pair of arms attached thereto and provided with frames at their free ends pressed toward each other with a yielding pressure, and sharpening-blades mounted in said frames and having their grinding-surfaces intersecting or crossing each other, substantially as described.

2. A knife-sharpener, comprising a base portion, a pair of arms attached thereto and provided with frames at their free ends held pressed

toward each other with a yielding pressure, and sharpening-blades mounted in said frames and having their grinding-surfaces converging with respect to each other, substantially as described.

3. A knife-sharpener, comprising a base portion, a pair of arms attached thereto and provided with frames at their free ends held pressed toward each other with a yielding pressure, and sharpening-blades mounted in said frames, and having their grinding-surfaces converging and intersecting or crossing each other, and beveled to provide a slicing mouth, substantially as described.

4. A knife-sharpener, comprising a base portion, a pair of arms attached thereto and provided with frames at their free ends held pressed toward each other with a yielding pressure, and sharpening-blades mounted in said frames and provided with interlocking or overlapping ribs having their inner faces adapted to operate upon the knife to be sharpened, substantially as described.

5. A knife-sharpener, comprising a base portion, a pair of arms attached thereto and provided with frames at their free ends held pressed toward each other with a yielding pressure, and sharpening-blades mounted in said frames and provided with interlocking or overlapping ribs; said ribs having their inner faces formed with teeth which extend in the same general direction when fitted together, substantially as described.

6. A knife-sharpener, comprising a base portion, a pair of arms attached thereto and provided with frames at their free ends held pressed toward each other with a yielding pressure, and provided with longitudinal grooves of gradually-varying width, and sharpening-blades corresponding in form to said grooves and fitting snugly therein, and having their inner or grinding faces converging with and intersecting each other, substantially as described.

7. A knife-sharpener, comprising a base portion, a pair of arms attached thereto and provided with frames at their free ends held pressed toward each other with a yielding pressure, sharpening-blades mounted in said frames and having their grinding-surfaces intersecting or crossing each other, and means for attaching the device to a suitable support, substantially as described.

8. In a knife-sharpener, a pair of frames held toward each other with a yielding pressure, said frames being formed at their inner or opposing sides with longitudinal grooves, whose sides converge inwardly or in the direction of the pressure applied as the knife-blade is forced down between them, and sharpening-blades of corresponding taper at their side edges and of size to fit snugly in said grooves, substantially as described.

9. In a knife-sharpener, a pair of frames held toward each other with a yielding pressure, said frames being formed at their inner or opposing sides with longitudinal grooves, whose sides converge inwardly or in the direction of the pressure applied as the knife-blade is forced down between them, and also inwardly toward the opposite frame, and sharpening-blades fitting snugly in said grooves and of corresponding contour as to be held reliably in the frames, substantially as described.

699,891. CAN OR LIKE CLOSURE. ARTHUR R. McWHART, Cleveland, Ohio. Filed Aug. 21, 1901. Serial No. 73,971. (No model.)

Claim.—1. A can or like closure having near its top an interior ledge or shoulder and a raised portion above said ledge or shoulder, a cover fitting within said raised portion and supported by said ledge, a bar extending across said cover to lock it in position, said raised portion of the can being formed upon its interior at one side with a seat for one end of said locking-bar and at its opposite side with a groove having an angular or offset portion to receive and retain the corresponding end of the locking-bar.

2. A can or like closure having upon its interior at one side of its top a groove open at one end to admit a locking-bar and formed with an angular or offset portion to hold said bar in locked position, the opposite side of the can-top being provided with means for engaging the other end of said locking-bar, a cover for the can and a locking-bar extending over said cover and engaging the top of the can.

3. A can or like closure having near its top an interior ledge or shoulder and a raised portion above said ledge or shoulder, said raised portion being provided within its interior with seats or depressions to receive the ends of a locking-bar, one of said seats or depressions being offset as at *f* to form a shoulder *f'* for holding the bar in locked position, a cover sitting within said raised portion and supported by said ledge and a locking-bar extending across said cover and having its ends within said seats or depressions.

4. A can or like closure having within its upper portion a metal ring extending over the top of the can-body and provided at a distance below said top with an inwardly-extending ledge or shoulder, said ring and said can-body being formed above said ledge or shoulder with seats or depressions to receive the ends of a locking-bar, one of said seats being formed with an offset portion to retain the locking-bar in position, a cover supported by said ledge or shoulder and a bar extending across said cover and having its ends within said seats or depressions.

699,892. SMUT-MACHINE. JOHN L. OWEN, Minneapolis, Minn.
Filed Feb. 4, 1901. Serial No. 46,511. (No model.)

Claim.—1. The combination, with a tank adapted to contain a supply of water and provided with a suitable hopper, of an inclined elevator-trunk within said tank beneath said hopper, a floor 18 in the bottom of said trunk whereon the grain falls from said hopper, a slatted elevator-belt adapted to sweep over said floor and carry the grain to the upper end thereof out of the water in the tank, a perforated plate or section provided near the upper end of said floor whereon the grain is partially drained before its discharge by said conveyor, a trough beneath the discharge end of said floor to receive the grain therefrom, a perforated floor therein whereon the grain falls and is drained a second time, and a slatted belt operating over said perforated floor to sweep the grain to the discharge end of said trough, substantially as described and for the purpose specified.

2. The combination, with a tank adapted to contain a supply of water and provided with a suitable hopper, of an inclined elevator-trunk within said tank beneath said hopper, a floor 18 in the bottom of said trunk whereon the grain falls from said hopper, a slatted elevator-belt adapted to sweep over said floor and carry the grain to the upper end

thereof out of the water in the tank, a trough 28 beneath the discharge end of said floor to receive the grain therefrom, a perforated plate 31 in the bottom of said trough whereon the grain falls and is drained of the water, a slatted belt operating over said plate to sweep the grain to the discharge end of said trough, and an impermeable plate 6 provided beneath said trough and plate and whereon the water drained from the wheat is conducted back to said tank, substantially as described and for the purpose specified.

3. The combination, with a tank adapted to contain a supply of water and provided with a suitable hopper, of an inclined elevator-trunk within said tank beneath said hopper, a floor 18 in the bottom of said trunk and whereon the grain falls from said hopper, a slatted elevator-belt adapted to sweep over said floor and carry the grain to the upper end thereof out of the water in the tank, a perforated plate or section provided in the upper end of said floor whereon the grain is partially drained of water before its discharge by said conveyor, a substantially horizontal trough 28 beneath the discharge end of said floor, a perforated plate 31 provided in the bottom of said trough and whereon the grain falls from said floor and is subjected to a second draining operation, a slatted belt operating over said plate to sweep the grain to the discharge end of said trough, and an impermeable plate 6 provided beneath said trough and perforated plate and inclined slightly toward said tank, whereby the drippings from said trough will be conducted back to said tank, substantially as described and for the purpose specified.

4. The combination, with a tank adapted to contain a supply of water and provided with a suitable hopper and a grain-elevating mechanism, of a sprocket-wheel supported on the wall of said tank, means for driving said wheel, a lever 44 pivoted eccentrically on said wheel and depending to a point near the water in said tank, a skimmer device 47 provided on the lower end of said lever and adapted to sweep over the surface of the water when said lever is elevated, a fixed arm 45 and a link 46 pivotally connecting said arm 45 and the upper end of said lever, whereby when said wheel is revolved a gyrating motion will be imparted to said lever and skimmer, for the purpose specified.

5. The combination, with a tank adapted to contain a supply of water and provided with a suitable hopper and grain-elevating device, of a gear-wheel supported on the wall of said tank, means for driving said wheel, a lever 44 eccentrically pivoted on said wheel and depending to a point near the surface of the water in the tank, a skimming device provided on the lower end of said lever and adapted to sweep over the surface of the water and gather up the smut thereon, a perforated plate provided on the wall of said tank whereon the smut is deposited by the action of said skimmer, and means connected with the upper end of said lever, whereby when said wheel is revolved said lever will be gyrated, substantially as described.

699,898. SMUT-MACHINE. JOHN L. OWEN, Minneapolis, Minn.
Filed Mar. 11, 1901. Serial No. 50,508. (No model.)

Claim.—1. An apparatus for destroying smut germs, comprising contacting rolls arranged one above the other each having a yielding porous covering, means for driving said rolls, means for delivering a chemical solution upon the upper roll, the lower-roll covering being saturated by the drippings from the upper roll, and means for delivering grain in a thin sheet between said rolls, substantially as described.

2. An apparatus for destroying smut germs, comprising two rolls arranged one above the other and each provided with a yielding porous covering, means for driving the lower roll, the upper roll being in contact

with the lower and driven thereby, means for delivering a chemical solution upon the surface of the upper roll is to be absorbed by the covering thereof and by the covering of the lower roll, means for delivering grain in a thin stream between said rolls, a dove to receive the grain from said rolls, and means for agitating said dove, substantially as described and for the purpose specified.

3. An apparatus for delivering said grain, comprising containing rolls arranged one above the other, each having a yielding porous covering, means for driving said rolls, a tank supported above said rolls, telescoping members provided beneath said tank and communicating therewith and each member having discharge-openings adapted to register and deliver the liquid in said tank upon the upper of said rolls, and means for delivering grain in a thin stream between said rolls.

699,894. METAL STRIP OR GRANT FOR USE IN MANUFACTURE OF CARDBOARD BOXES. MAX R. FARMER, Dresden, Germany. Filed Sept. 12, 1897. Serial No. 661,494. (No model.)

Claim.—1. As an improved article of manufacture, a flat-bellied metallic fastening-strip having its extreme edge depressed at intervals, the material from the depressions forming teeth projecting at substantially right angles to the plane of the body of the strip, with a space between adjacent teeth, each of said teeth being bent in cross-section in a plane parallel with the plane of the body of the strip the base-line of each tooth starting from the original edge of the strip and returning to it; substantially as described.

2. As an improved article of manufacture, a metallic fastening-strip having its edges depressed at intervals, the material from the depressions forming teeth projecting at substantially right angles to the plane of the body of the strip and the sides of each of the teeth extending along the edges of both adjacent projections left by the depressions, whereby a tooth bent in cross-section is formed; substantially as described.

699,895. AUTOMATIC PAPER-COLLECTING APPARATUS FOR STREET-CARS OR OTHER PUBLIC VEHICLES. LEONARD FARMER, Vienna, Austria-Hungary. Filed July 12, 1900. Serial No. 94,900. (No model.)

Claim.—1. The combination in a vehicle of means for permitting entrance but barring exit, means for permitting exit but barring entrance, a passage between the two, and coin-controlled step-by-step mechanism blocking said passage except upon the deposit of a suitable coin.

2. The combination, in a vehicle, of a turnstile permitting entrance and barring exit, a turnstile permitting exit and barring entrance, and an intermediate coin-controlled turnstile having passage between the other two except when released upon the deposit of a suitable coin.

3. The combination, in a vehicle having and platform, of two turnstiles on each platform, one barring exit and permitting entrance, and the other barring entrance and permitting exit, the corresponding turnstiles for each platform being arranged diagonally opposite each other, and an intermediate coin-controlled turnstile placed between the platforms and blocking the only passage from the entrance-turnstiles to their relative exit-stiles.

4. The combination of the entrance-turnstiles at one end of the car or vehicle, arranged to bar exit, the exit-turnstiles at the other end of the car or vehicle, arranged to bar entrance, the partition dividing the car into front and rear compartments, and the coin-controlled turnstile blocking the passage between these compartments.

699,896. UNDERGARMENT. FRANK J. FINE, Worcester, R. I. Original application filed Sept. 25, 1891, Serial No. 74,000. Divided and this application filed Mar. 2, 1902. Serial No. 97,500. (No model.)

Claim.—A garment having a front, buttoned opening extending down to the feet, and also having an opening in its rear communicating with the front, buttoned opening and extending upwardly from the crotch, and cut portion, the flap B joined along its vertical edge to one of the cut portions at one edge of the rear-opening and extending throughout the latter, means for detachably connecting the free portion of said flap to the body of the garment, and a supplemental flap forming a continuation of the inner layer of the buttoned front of the garment joined along its vertical edge to the cut portion opposite to that to which the flap B is joined, and joined at its upper end to the body of the garment; the said supplemental flap being arranged to normally rest within the flap B.

699,897. ANALYTIC BANDAGE. THOMAS L. RAY, Fort Worth, Tex. Filed Apr. 9, 1891. Serial No. 64,900. (No model.)

Claim.—1. A bandage consisting of strips adapted to circumscribe the head and having a cushion and pads attached to the inside thereof, and means for protecting the ear from the pressure of the strips, said strips being provided with suitable buckles whereby said pads may be adjusted to press on the nerve centers about the head for controlling the flow of blood through the head and the face.

2. A bandage provided with strips adapted to circumscribe the head, pads attached to the inside of the strip passing around the lower back part of the head at points adjacent to the vasomotor nerve centers at the base of the skull, said rings circumscribing the ear for protecting the ear from the pressure of said strips, said strips being attached to said rings.

3. A bandage consisting of a strip adapted to pass around the lower

back part of the head and having two pads attached to the inside thereof adjacent when in position to the vasomotor nerve centers at the base of the skull, a ring circumscribing each ear, said strip adapted to pass said pads against the head and being adjustably attached to said rings and connected together in front of the forehead whereby said strips hold said rings in place and draw said pads against the head, and a forehead-strap adjustably mounted on the inside of said strips for protecting the forehead from said strips.

699,898. REGISTER. RICHARD HANSEN, Christiania, N. Filed Jan. 28, 1892. Serial No. 61,900. (No model.)

Claim.—In a register, the combination of a case having an opening and a glass in its front wall; said glass being provided with a pointer, a rotary disk mounted in the case opposite the glass and having numbered divisions on its face, a rotary disk also mounted in the case and having a circular series of consecutive numbers on its face arranged to be exposed through the opening of the case, means for rotating the first-mentioned disk, a case fixed with respect to said disk and having a notch in its periphery, a ratchet fixed with respect to the second-mentioned disk, the flat spring I connected at one end to the case and having its free end disposed against the periphery of the case and adapted to lateral, flat spring into the notch thereof, and also having the spring-arm F arranged in engagement with the ratchet, and means for preventing retrograde movement of the rotary disk.

699,899. ELECTRIC METER. GEORGE A. SCHNEIDER, Perth, N. S. W., assignor to the Diamond Meter Company, Perth, N. S. W. Filed Jan. 10, 1900. Serial No. 1,001. (No model.)

Claim.—1. In a meter, the combination with the armature-winding thereof, of a shaft upon which the armature-winding is rotatably mounted, a yoke 14 secured to the shaft, a cylindrical contact-pin located in axial alignment with the shaft, said contact-pin constituting a terminal of the armature-winding, a brush engaging the said contact-terminal for connecting a terminal of the armature-winding with one side of a distribution-circuit, and means for connecting the other terminal of the armature-winding with the remaining side of the distribution-circuit, substantially as described.

2. In a meter, the combination with the armature-winding thereof, of a shaft upon which the armature-winding is rotatably mounted, a yoke

14 secured to the shaft, an insulating portion 12 carried by the yoke, a cylindrical contact-pin secured to the said insulating portion and placed in axial alignment with the shaft, said pin having connection with the terminals of the armature-winding, and contact-brushes for engagement with the pin to include the armature-winding in circuit, substantially as described.

3. In a meter, the combination with the armature-winding thereof, of a shaft upon which the armature-winding is rotatably mounted, a yoke 14 secured to the shaft, an insulating portion 12 carried by the yoke, a cylindrical contact-pin secured to the said insulating portion and placed in axial alignment with the shaft, said pin having threaded engagement with the insulating portion, and nuts 13; 13 also having threaded engagement with the pin, terminal wires of the armature-winding being secured in electrical connection with the contact-pin through the agency of said nuts, substantially as described.

4. In an oscillating electric meter, the combination with the oscillating member thereof mounted upon a rotating shaft, of an arm movable with the oscillating member, an electromagnet, means controlled thereby for effecting the movement of the oscillating member of the meter in a direction reverse to the direction of rotation due to the torque-producing means of the meter, the said arm being adapted to come in contact with a terminal of the electromagnet to close circuit therewith, a yoke 14 carried by the shaft of the oscillating member, a cylindrical contact-pin carried by the said yoke in axial alignment with the said shaft, said pin having electrical connection with the said arm, and a brush for connecting the said electrical contact-pin with one side of the transmission-circuit, the remaining terminal of the electromagnet being suitably connected with the remaining side of the transmission-circuit, substantially as described.

699,900. APPARATUS FOR SETTING TIME-PURSE. CHARLES P. R. SCHNEIDER and JOHN R. G. A. GARDNER, Le Grand, France. Filed June 12, 1891. Serial No. 64,901. (No model.)

Claim.—1. In apparatus for setting time-purse, a casing, two members rotatably mounted in said casing, locking means for holding one of said members in any desired position of adjustment in the casing, manually-operable means for rotating the other member, and catches one on each member adapted to engage respectively with and temporarily lock the members to the two parts of the face which are relatively adjustable to give the desired setting.

2. In apparatus for setting time-purse, a casing, two members rotatably mounted in said casing, locking means for holding one of said members in any desired position of adjustment to which it is rotated, manually-operable means for rotating the other member, a stop device acting to arrest the rotation of said other member when it reaches a certain predetermined position, and a catch on each member adapted to engage respectively with and temporarily lock the members to the two relatively movable parts of the face.

3. In apparatus for setting time-purse, a casing, two members rotatably mounted therein, manually-operable gearing for rotating one of said members to any desired position of adjustment and for locking it in said position, manually-operable means for rotating the other member, a stop device acting to arrest the rotation of said member when it reaches a certain predetermined position, and a catch on each member adapted to engage respectively with and temporarily lock the members to the two relatively movable parts of the face.

4. In apparatus for setting time-purse, a casing, two hollow members rotatably mounted therein adapted to embrace a face inserted therein, manually-operable means for rotating one of said members to any desired position of adjustment, manually-operable means for rotating the other member, and a spring-actuated catch on each member adapted to engage respectively with and temporarily lock the members to the two relatively movable parts of the face.

5. In apparatus for simultaneously setting two time-purse, a casing, two members in said casing each comprising two hollow rotatable members adapted to embrace a face inserted therein, manually-operable means common to both mechanisms for simultaneously rotating one of the members of each mechanism to any desired position of adjustment, manually-

operable means common to both mechanisms for simultaneously rotating the other member of each mechanism, spring-actuated catches on each member adapted to engage respectively with and temporarily lock the members in the relatively movable parts of the frame.

699,901. MIRROR-BRACKET. SVENNE SVENSSON, Sweden. Filed July 5, 1901. Serial No. 67,532. (No model.)

Claim.—1. A mirror-bracket comprising a mirror-supporting bar bent between its ends to provide oppositely-inclined members, side supports having braces at their lower ends for engagement with the back of the mirror, forwardly-extending shoulder-hooks arranged about midway of the ends of the said side supports, and an adjustable transverse connection forming a tie for the said side supports, substantially as specified.

2. A mirror-bracket formed of a single length of wire and comprising a transverse mirror-supporting bar having its end portions oppositely inclined, side members having their upper portions upwardly diverged and their lower parts constituting braces for engagement with the back of the mirror, shoulder-engaging hooks extended forward from the side members at a point intermediate of their ends, and a transverse connection forming a tie for the said side members, substantially as described.

699,902. RAIL-BOND CONSTRUCTION. EDWARD S. THOMAS, Cambridge, Mass. Filed Nov. 1, 1901. Serial No. 59,742. (No model.)

Claim.—1. A rail-bond consisting of a flexible strip, having portions of its length between its ends bent laterally, sufficiently to pass through the web of a rail.

2. A rail-bond consisting of a flexible strip, having its ends located in different planes, corresponding to the opposite sides of the web of a rail.

3. A rail-bond consisting of a flexible strip bent laterally between its ends and thereby adapted to be passed through an opening in one or both of the rails to be joined, and to be attached at each end to one of the rails.

4. In a rail-bond, a combination of two attaching-surfaces and a flexible portion bent in the direction toward which one or both of the said surfaces face, and thereby adapted to pass through the web of a rail.

5. In a rail-bonding construction, the combination with rails provided with a perforation, of a flexible connection secured to said rails and passing through said perforation.

6. In a rail-bonding construction, the combination with rails provided with an opening leading from one side to the other thereof, of a flexible strip passing through said opening and secured at its ends to the opposite sides of said rails.

699,903. RAIL-JOINT. JOHN THORNTON, Butler, Iowa. Filed Mar. 2, 1902. Serial No. 65,982. (No model.)

Claim.—1. In a rail-joint, a member having spaced longitudinal extensions, and a mortise extended inward from the extremity of the rail and opening upward through the tread-surface, and the other member having the foot of the rail cut away at each side of the web to receive the said extensions, which embrace the sides of the web, and a longitudinal extension to fit within the said mortise, substantially as set forth.

2. In a rail-joint, a member having spaced longitudinal extensions, and a mortise extended inward from the extremity and having its side walls upwardly flared, and the mating member having the foot cut away at each side of the web to receive the said extensions and having a longitudinal extension with its sides upwardly diverged to snugly fit the said mortise, substantially as set forth.

3. In a rail-joint, a member having spaced longitudinal extensions and a mortise, the mating member having a portion of the foot cut away upon each side of the web to receive the said extensions and having a longitudinal extension to snugly fit said mortise, and splice-plates secured to opposite sides of the joint and having offsetting wings to be attached to a tie, each of the splice-plates having an offset portion to fit a cut-away part of the foot of the rail member forming the joint, substantially as set forth.

699,904. UNIVERSAL JOINT. RICHARD C. WARREN, Hartford Conn. Filed Jan. 2, 1902. Serial No. 64,494. (No model.)

Claim.—1. In a universal joint, the combination, with a flanged shaft having headed studs, of a sectional connecting-block having grooves for the reception of the heads of said studs; a second shaft; and means for uniting said second shaft to said connecting-block.

2. In a universal joint, the combination, with a shaft having inwardly-projecting arms, of headed studs carried by said arms; a sectional connecting-block fitted to said shaft, each section being grooved to receive the studs; a second shaft having projecting arms; and means for uniting the shafts and sectional connecting-block.

3. In a universal joint, the combination, with a shaft having arms, of headed studs projecting inwardly from said arms; a sectional connecting-block, each section having grooves for the reception of the heads and shanks of said studs; a second shaft; and means for uniting said second shaft to the connecting-block.

4. In a universal joint, the combination, with a shaft having arms at its end, of headed studs carried by said arms; a sectional connecting-block having grooves for the reception of said studs, each section of said block being perforated; a second shaft having perforated arms; and a bolt for securing said shaft to the connecting-block, said bolt passing through the aligned perforations of the connecting-block.

5. In a universal joint, the combination, with a shaft having arms, of headed studs carried by said arms; a sectional connecting-block having grooves for the reception of said studs, each of the sections of said block being perforated; a second shaft having perforated arms; and means passing through the perforations of said arms and block for securing the parts together.

6. In a universal joint, the combination, with a shaft having arms, of headed studs carried by said arms; a sectional connecting-block, the sections of said block having grooves for the reception of the headed studs and being perforated; a second shaft having perforated arms, one of which is threaded; and a bolt having a thread at one of its ends for engaging with said threaded arm, said bolt passing through the perforations of the sectional connecting-block and serving to unite the parts, substantially as set forth.

7. In a universal joint, the combination, with a shaft secured at its end and having arms, of laterally-projecting, headed studs carried by said arms; a sectional connecting-block, each section of the block having grooves for the reception of the studs and also having lubricating passages, and each of said sections being perforated; a second shaft secured at its end and having perforated arms, one of said arms being laterally threaded; and a bolt having a screw-thread at its end, and serving to unite said shaft with the connecting-block.

8. The combination, with devices having flanged ends, of studs, each having a projection, carried by one of said devices; a sectional block, each section of which is shaped to receive the studs and is also perforated; and a bolt passing through one of the flanged devices and through the sectional block, said bolt bearing against the projections of the studs.

9. The combination, with devices, each having a pair of arms, one pair of said arms being perforated, of devices uniting laterally from the

other pair of said arms, said devices having projections, a sectional block having grooves to receive the projections, each section of said block being perforated; and a bolt passing through the perforations of the arms and block-sections and bearing against said projections.

699,905. RAIL-JOINT END-PLATE. JOHN E. WHITNEY, Johnstown, N. Y. Filed Aug. 28, 1901. Serial No. 73,795. (No model.)

Claim.—In a rail-joint end-plate consisting of a flat metal strip of about the same width as the flange of the rail, a turned-over portion formed upon one side of the strip, another turned-over portion formed upon the other side of the strip, an extension formed upon each end of the strip, and a tie passing through the perforations of the said ends and block for securing the parts together, substantially as and for the purpose specified.

699,906. RAILROAD WAGON AND RECEIPTAGE. CHARLES A. WILLIAMS, Chicago, Ill. Filed Sept. 25, 1901. Serial No. 74,046. (No model.)

Claim.—1. In a device of the class described, the combination with the wheels and running-gear, of a vertical frame carried thereby, and plural rows of supports for garbage-receptacles on both sides of said frame; substantially as and for the purpose described.

2. In a device of the class described, the combination with the wheels and running-gear, of a vertical frame carried thereby, and plural rows of supports on both sides of said frame, each of said supports consisting of a horizontal ring secured at one edge to said frame and having the vertical flange on the outer edge thereof; substantially as described.

3. In a device of the class described, the combination with the wheels and running-gear, of a vertical frame carried thereby, and plural rows of supports on both sides of said frame, said supports consisting of the horizontal rings secured at one edge to said frame and the brackets 25 secured to said frame and to said rings; substantially as described.

4. In a device of the class described, the combination with the vertical frame, of the supports formed of strips of angle-iron bent into circles and secured at one side thereof to said frame, and the said brackets 25 secured to said frame between the supports; substantially as described.

5. In a device of the class described, the combination with the vertical frame, of the supports consisting of the horizontal rings secured at one edge to said frame and having the vertical flange on the outer edge thereof; substantially as described.

thereof, and the brackets 15 secured to said frame above the points where the rings touch the frame; substantially as described.

6. In a device of the class described, the combination with the vertical frame, of the supports consisting of the horizontal rings secured at one edge to said frame and having the vertical flange on the outer edge thereof, the brackets 25 secured to said frame and to said rings, and the brackets 15 secured to said frame above the points where the rings touch the frame; substantially as described.

7. In a device of the class described, the combination with a receptacle having the loop 9 formed in the upper edge thereof, of the lid having the loop 14 in the edge thereof engaging with the loop 9; substantially as and for the purpose described.

8. In a device of the class described, the combination with a receptacle having the ring 7 in the upper edge thereof, said ring being provided with the loop 9 thereof, of the lid having the ring 11 in the edge thereof, said ring being provided with the loop 14 engaging the loop 9; substantially as and for the purpose described.

9. In a device of the class described, the combination with the vertical frame, of the supports secured at one edge to said frame and having the vertical flange on the outer edge thereof, the brackets 15 secured to said frame above the points where the supports touch the frame, the receptacles having their lower ends adapted to fit in said supports and provided with the loops 9 in the upper edge thereof, the lids for said receptacles having the loops 14 engaging the loops 9, which are also adapted to engage the brackets 15; all combined and co-operating substantially as and for the purpose described.

699,907. ELECTROLYTIC APPARATUS FOR MANUFACTURING CERTAIN SALTS SUITABLE FOR THE SUBSEQUENT PRODUCTION OF CHLORINE. GEORGE J. AHERN, London, England. Filed Aug. 17, 1901. Serial No. 74,055. (No model.)

Claim.—Electrolytic apparatus for manufacturing certain salts suitable for the subsequent production of chlorine which consists of a long trough-like vessel *a* lined with a tubular member *b*, a cylinder *c* secured in said vessel forming a cathode arranged to rotate in the trough-like vessel *a*, a connection *d*, with a source of electricity arranged to deliver a current of not more than ten volts of electro-motive force to the electrolyte, a flexible scraper *e* to remove the adhering electrolyte solution and the bubbles of hydrogen from the rotating cathode, an inlet *f* for electrolyte solution at one end of the trough and an outlet *g* for same at the opposite end of the trough, substantially as described.

699,908. HAND-OUTTER AND FEEDER FOR THRESHING-MACHINES OR GRAIN-SEPARATORS. WILLIAM SHANNON, Kansas, Canada. Filed Sept. 12, 1901. Serial No. 74,594. (No model.)

Claim.—1. In a hand-outter and feeder, the combination of a cranked shaft, a feeder-board having one end connected with the crank on said shaft and its other end mounted to revolve, a sprocket-wheel carried by the crank of the shaft, a second sprocket-wheel carried upon bearings in the feeder-board, endless conveyor-chains passing over both said sprocket-wheels so as to be operated by the revolving motion of the cranked shaft simultaneously with the reciprocation of the feeder-board, and revolving cutter-knives hinged on the shaft of the second sprocket-wheel and operating in slots in said feeder-board.

2. In a hand-outter and feeder, the combination of a double-cranked shaft having its two cranks oppositely disposed upon the axle of the shaft, a pair of feeder-boards, one mounted on each of said cranks, a sprocket-wheel carried by each crank, a second sprocket-wheel mounted on a shaft carried rearwardly of said first sprocket-wheel upon each feeder-board and operating in a slot therein, an endless band or chain passing over each of said sprocket-wheels upon each feeder-board and carrying means for transporting the grain, a series of rotary cutters mounted on the shaft of the rearward sprocket-wheel in each feeder-board and operating in slots therein, a series of backwardly-directed pointed ledges or curvatures on the upper face of each feeder-board, and means for reciprocally supporting the rear end of each feeder-board, whereby the feeder-boards alternate with one another in their back-and-forth movements and the conveyor-chains and cutters are continuously operated.

3. In a hand-outter and feeder, a feeder-board having backwardly-facing curvatures or ledges upon its upper surface and a downwardly-bent

rear portion, a cranked shaft on which said roller-board is supported at one end, a pivoted link on which the other end of roller-board, a sprocket or gear wheel attached to the crank of the shaft, a second parallel shaft carried in bearings on the roller-board at the head thereof and close to the face of the roller-board, a sprocket or gear wheel carried thereon, endless chains or conveyor-belts passing over the face of the roller-board and around said sprocket-wheel and under its rear side through slots thereof, rotary cutters mounted on said last-mentioned shaft and likewise operating through slots adjacent to the head in the roller-board, and means for reciprocally supporting the rear end of the roller-board as described.

4. In a head-cutter and feeder, a cranked shaft adapted for the application of power, a feeder-board having an angular head intermediate thereof causing the rear portion to be downwardly and rearwardly deflected, bearings connecting the front end of said feeder-board with the cranked portion of said shaft, sprocket-wheel carried by said cranked portion, a transverse shaft journaled on said feeder-board close to the face thereof and adjacent to said angular head, sprocket-wheel and rotary cutters mounted on said shaft and operating through suitable slots in the feeder-board, endless conveyor belts or chains passing over both series of sprocket-wheel and having their upper runches close to the face of said board and their lower runches passing through said slots and around the lower face of said board, and laterally-feeding ridges or corrugations projecting from the upper face of said board along the length of the conveyor-chains and at each side thereof.

5. In a head-cutter and feeder, a cranked shaft adapted for the application of power, a feeder-board attached at its forward end to the cranked portion of said shaft and having its other end reciprocally mounted, sprocket-wheel carried by the cranked portion of said shaft, a transverse parallel shaft mounted midway of the feeder-board and carrying sprocket-wheel and rotary cutters, each operating through suitable slots in the feeder-board, conveyor-chains passing over said sprocket-wheel and adapted simultaneously to carry forward the grain placed upon said table and to operate said rollers to cut the heads, hicker-blades pivoted upon a second transverse shaft rearwardly of said first-mentioned shaft, and means for reciprocally said hicker-blades to open the grain after the operation of the cutter-blades.

6. In a head-cutter and feeder, a cranked shaft adapted for the application of power, a feeder-board supported by bearings at its forward end and to the cranked portion of said shaft and having its opposite end reciprocally mounted, sprocket-wheel carried by the cranked portion of said shaft, a transverse shaft mounted midway of the feeder-board adjacent to its face, sprocket-wheel and rotary cutter-blades mounted on said second shaft and operating in slots in the feeder-board, a chain conveyor passing over said sprocket-wheel and adapted to operate said rollers and to be operated by the turning of the cranked shaft, said chain conveyor having its upper runch passing over the face of said feeder-board and its

lower runch beneath the same and through the slots therein, and hicker-blades mounted on a transverse shaft rearwardly of said first transverse shaft and adapted to be opened to throw the grain upwardly and rearwardly toward the thrasher, substantially as described.

7. In a head-cutter and feeder, a cranked shaft adapted for the application of power, a feeder-board supported by bearings at its forward end and to the cranked portion of said shaft and having its opposite end reciprocally mounted, sprocket-wheel carried by the cranked portion of said shaft, a transverse shaft mounted midway of the feeder-board adjacent to its face, sprocket-wheel and rotary cutter-blades mounted on said second shaft and operating in slots in the feeder-board, a chain conveyor passing over said sprocket-wheel and adapted to operate said rollers and to be operated by the turning of the cranked shaft, said chain conveyor having its upper runch passing over the face of said feeder-board and its lower runch beneath the same and through the slots therein, a second transverse shaft mounted rearwardly of the first, cutter-shaped hicker-blades mounted on said second shaft and projecting forwardly through appropriate slots in the feeder-board, and means connecting said blades with a stationary point of the apparatus, whereby the reciprocation of the feeder-board causes the blades to be thrown up to project the grain upwardly and rearwardly.

8. In a head-cutter and feeder, a cranked shaft adapted for the application of power, a feeder-board having an angular head intermediate thereof causing the rear portion to be downwardly and rearwardly deflected, bearings connecting the front end of said feeder-board with the cranked portion of said shaft, sprocket-wheel carried by said cranked portion, a transverse shaft journaled on said feeder-board close to the face thereof and adjacent to said angular head, sprocket-wheel and rotary cutters mounted on said shaft and operating through suitable slots in the feeder-board, endless conveyor belts or chains passing over both series of sprocket-wheel and having their upper runches close to the face of said board and their lower runches passing through said slots and around the lower face of said board, and laterally-feeding ridges or corrugations projecting from the upper face of said board along the length of the conveyor-chains and at each side thereof.

9. In a head-cutter and feeder, a cranked shaft adapted for the application of power, a feeder-board having an angular head intermediate thereof causing the rear portion to be downwardly and rearwardly deflected, bearings connecting the front end of said feeder-board with the cranked portion of said shaft, a transverse shaft journaled on said feeder-board close to the face thereof and adjacent to said angular head, sprocket-wheel and rotary cutters mounted on said shaft and operating through suitable slots in the feeder-board, endless conveyor belts or chains passing over both series of sprocket-wheel and having their upper runches close to the face of said board and their lower runches passing through said slots and around the lower face of said board, a transverse shaft journaled upon the lower face of said feeder-board rearwardly of said cutters, cutter-shaped hicker-blades mounted on said shaft and projecting forwardly thereof, a crank-arm hinged to said last-mentioned shaft and attached to a stationary point of the apparatus, and a link having a stationary bearing at one end and supporting the feeder-board at the other end so as to permit the latter to oscillate or reciprocate thereon.

10. In a head-cutter and feeder, the combination of a plurality of feeder-boards, a grain-table having a longitudinal partition, a pair of sprocket-wheel for each feeder-board, one at each end of said partition and parallel therewith, a head-conveyor for each feeder-board passing over said sprocket-wheel and having its upper runch passing adjacent to the edge of the partition, and means for operating said conveyor-chains, whereby to push the grain off of the edge of said partition.

11. In a head-cutter and feeder, the combination of a plurality of feeder-boards, a grain-table having a longitudinal partition, a pair of sprocket-wheel mounted one at each end of the partition and parallel therewith, a head-conveyor for each feeder-board passing over said sprocket-wheel and having its upper runch adjacent to the upper edge of said partition, feeding means on the table for pushing forward the grain, and means for operating the head-conveyor at a different rate of speed from said feeding means, whereby to push the grain from the edge of said partition and throw it onto the table.

12. In a head-cutter and feeder, the combination of a grain-table having feeding means adapted to carry forward the grain thereon, a partition longitudinal thereof, a sprocket-wheel mounted at each end of the partition and in line therewith, an endless conveyor-chain passing over said sprocket-wheel and having its upper runch passing along the top edge of said partition, and means for operating said conveyor-chains at a different speed from the feeding mechanism, whereby to push off the grain helping on said partition.

13. In a head-cutter and feeder, the combination of a grain-table having endless conveyor-belts thereon adapted to push forward the grain, a partition longitudinal thereof and carrying at each end a sprocket-wheel parallel therewith, a head-conveyor carried on said sprocket-wheel and

having its upper runch extending along the upper edge of the partition, and means connecting said conveyor-belts with said head-conveyor, whereby said head-conveyor is moved faster than the feeder-blades to push off the grain helping on the partition.

14. A grain-table for head-cutter and feeder comprising a frame carrying at each end a transverse shaft, small and large sprocket-wheel carried by said shaft, endless conveyor-belts passing over said smaller sprocket-wheel, a longitudinal partition between said conveyor-belts, an idle sprocket-wheel carried at each end thereof and in line therewith, and a head-conveyor carried over said idle sprocket-wheel and adjacent to the upper edge of the partition and having its lower runch engaging said large sprocket-wheel, whereby to drive the head-conveyor at a faster rate than said conveyor-belts.

15. A head-cutter and feeder comprising a cranked shaft adapted for the application of power, a feeder-board connected at its forward end to the cranked portion of said shaft and reciprocally mounted at its rear end and having a downwardly-bent rear portion, sprocket-wheel carried by the cranked portion of said shaft, a transverse shaft mounted intermediate of said feeder-board in the upper face thereof and over the angle of said bend, sprocket-wheel and rotary cutters mounted on said shaft and operating through slots in said feeder-board, conveyor-chains passing over said sprocket-wheel and adapted simultaneously to move forward the grain and to rotate said cutters upon the turning of the said cranked shaft and reciprocally said feeder-board, a shaft journaled upon the under face of said feeder-board transversely of the cutters, hicker-blades mounted on said shaft and extending forwardly thereof and oscillating through slots in the feeder-board to project the grain upwardly and rearwardly, means connecting said shaft with a stationary point on the opposite side, a grain-table overlapping the forward end of said feeder-board and having a transverse shaft in each end thereof, the rearward shaft being extended to form pivots for said table, whereby the same may be turned into upright position, differential sprocket-wheel carried by said transverse shaft, endless conveyor-belts mounted on the smaller of said wheels, a longitudinal partition on said grain-table, idle sprocket-wheel carried at each end thereof, a head-conveyor passing around said idle sprocket-wheel and adjacent to the upper side of said head-conveyor, and having its lower runch engaging with the larger of said differential sprocket-wheel, and a step 73 attached to the frame of the machine, whereby said grain-table may be turned about its rearward shaft as a pivot and retained in a nearly vertical position, substantially as described.

699,909. FLEISSA. FRANK BERNARDSON, Detroit, E. Y. Filed Mar. 20, 1899. Serial No. 69,909. (No model.)

Claim.—1. In a pliers, a pair of handles pivoted together, a pair of jaws pivoted together independent of said handles, plates arranged in pairs upon each side of the handles and jaws, said plates crossing one another and being pivoted together upon the same pivot as the jaws, one end of said plates upon each side being connected to the jaws, the heel end of the plates upon each side being connected to the handles, substantially as described and for the purpose specified.

2. In a pliers, a pair of handles pivoted together, a pair of jaws pivoted together at their heel ends independent of the handles, a pair of plates, one upon each side of the jaws and handles, one end of said plates being pivoted to one of the jaws, the other end of said plates being pivoted to one of the handles, a second pair of plates, one upon each side of the jaws and handles, said second pair of plates adapted to cross the first-mentioned pair of plates and to be pivoted at one end to the other jaw and at their other end to the other handle, said plates being all pivoted together upon the same pivot as the jaws, cutting-edges curved to or formed with said side plates, the cutting edges adapted to meet and be parallel with one another when the jaws are closed, substantially as described and for the purpose specified.

3. In combination, to pliers, a pair of handles A pivoted together, a pair of jaws B pivoted together independent of the handles, one plate C arranged in pairs upon each side of the jaws and handles and pivoted upon the same pivot as the jaws, one end of said plates, one upon each side of the jaws being pivoted at one end to one of the jaws at a point between the pivotal point of the jaws and the end of the jaws, the other end of the same plates being pivoted to one of the handles at a point intermediate of the pivotal point of said handles and their ends, the other two plates, one upon each side of the jaws, being pivoted at one of their ends to the other jaws at a point intermediate between the pivotal point of the jaws

and the end of the jaws, and the other end of the same plates being pivoted to the other handles at a point intermediate of the pivotal point of the handles and their ends, wire-cutters curved to or formed with one side of the jaws having cutting edges adapted to meet and be parallel with one another when the pliers are closed, substantially as and for the purpose specified.

699,910. FLEISSA. AND HAN WHEEL. BOSTON. JOHN T. O'NEILL, Worcester, Mass., assignor to Crumpton & Knowles Loom Works, Worcester, Mass., a Corporation of Massachusetts. Filed Dec. 20, 1899. Serial No. 71,001. (No model.)

Claim.—1. In a pin-wheel and star-wheel motion, a pin-wheel having a driver-pin, a curved flange or extension, and two shorter pins, the three pins being on the same arc of a circle and equal distances from each other, and a star-wheel, having radial slots in its periphery, and concave recesses or depressions intermediate said slots, and curved flanges or extensions on one side near the edge, substantially as shown and described.

2. In a pin-wheel and star-wheel motion, a pin-wheel, having a driver-pin, a curved flange or extension, and two shorter pins, the three pins being on the same arc of a circle, and equal distances from each other, and a star-wheel, having radial slots in its periphery, and concave recesses or depressions intermediate said slots, and curved flanges or extensions on one side near the edge, the width of said flanges being a little less than the width or distance between the curved flanges on the pin-wheel and the two shorter pins thereon, substantially as shown and described.

3. In a pin-wheel and star-wheel motion, means for locking or holding the star-wheel in position during its rest or dwell, consisting of a curved flange or extension on the pin-wheel, two shorter pins on the pin-wheel, in the same arc of a circle as the driver-pin, and equal distances apart, and a curved flange or extension on the star-wheel, which extends between the two shorter pins and the curved flange on the pin-wheel, when the star-wheel is at rest, substantially as shown and described.

699,911. CLARK. CALVIN E. DAVIS, South Bend, Ind., assignor to Oliver Chilled Iron Works, South Bend, Ind. Filed Jan. 26, 1899. Serial No. 91,908. (No model.)

Claim.—1. A red-clamp comprising a sleeve to receive the rod, a housing open at its ends and located in the outer face of the sleeve and communicating therewith, and a wedge adapted to be inserted at one end of said housing and project at the other and clamp the rod in the sleeve.

2. A red-clamp consisting of a sleeve to receive the rod, a housing open at its ends and located in the outer face of the sleeve and communicating therewith, a wedge adapted to be inserted at one open end of

and bearing and project at the other end, and a nut on said projecting end for moving the wedge longitudinally.

3. A clamp for a rod comprising a sleeve to receive the rod a bearing open at its ends and hinged in the center face of the sleeve and communicating intermediate its ends with same, the said bearing having a flat inner face, an angular clamping-belt adapted to be inserted through one end of the bearing and project through the other open end, and a nut screwed onto the projecting end of said clamping-belt.

4. A collar or jointer clamp, comprising a metal plate adapted to be secured to the beam of a press, a sleeve integral with said plate to receive a collar or jointer supporting-rod, a bearing on the sleeve, communicating therewith and having an angular base or channel and an angular opening in one end, a clamping-belt in said bearing made angular and wedge shape throughout a portion of its length to wedge between the bearing and rod, a cylindrical screw-threaded end on said belt projecting through one end of said bearing and a nut screwed onto said belt.

699,912. HYDROCARBON-BURNER. CHARLES E. DE VERA, Oakland, Cal. Filed Sept. 20, 1901. Serial No. 75,712. (No model.)

Claim.—1. The combination in a hydrocarbon-burner of a reservoir containing liquid and air under pressure, a pipe extending to the bottom of the reservoir having openings at the lower end through which the liquid may enter, a burner leading from said pipe upwardly and across above the burner-chimney which is carried by the lamp, said pipe having a fitting of wire-gauge whereby the liquid is divided and heated, a discharge-pipe through which the vapor is delivered, a second pipe located with its end in line to receive the discharge from said burner, adjustable intake caps connecting the two pipes having openings and means by which said openings are made to coincide or be partially closed to regulate the supply of air which is admitted, a cap into which the second pipe discharges and in which the air and vapor are mixed, an exterior cap enclosing the first-named one having the pipe leading therefrom to the burner.

2. The combination in a hydrocarbon-burner of a reservoir in which liquid and air under pressure are contained, a burner and chimney carried upon said reservoir, a pipe connecting with the bottom of the reservoir having a valve through which a regulated amount of liquid is allowed to pass, said pipe extending above the burner so as to be heated thereby, and containing a body of wire-gauge, a jet-nozzle through which the vapor is discharged from said pipe, a second pipe in line with said nozzle, and means for admitting and regulating the supply of air thereto, a valve consisting of an exterior chamber closed at the top having a pipe leading from the bottom and connecting with the burner, and an inner cap or chamber supported out of contact with the sides of the outer one, into the bottom of which the pipe receiving the vapor and air discharges whereby the mixing is effected, said inner cap being open at the top so that the mixed products must take a tortuous direction to the burner-pipe.

3. The combination in a hydrocarbon-lamp of a reservoir for liquid and air under pressure, a burner supported thereby, a mixing-chamber including concentric cups supported out of contact with each other, for mixing vapor and air, and a pipe leading from the outer cup to the burner, a pipe connecting with the reservoir through which the liquid is forced, said pipe crossing above the lamp-chimney so as to be heated thereby, and also passing in contact with the mixing-chamber so that the temperature of the liquid is elevated before it reaches the point where it is vaporized.

4. The combination in a hydrocarbon-lamp of a reservoir adapted to contain liquid, and a means for admitting a stated quantity of liquid there-

and air under pressure, a plurality of burners supported upon said reservoir having nozzles and a chimney common to both, a pipe extending upwardly from the bottom of the reservoir having openings by which the liquid is admitted therein, valve-controlled branches extending from said pipe upwardly and crossing above the burner-chimney whereby they are heated and the liquid vaporized, jets through which the vapor is discharged from each pipe, mixing-chambers including concentric cups supported out of contact with each other, pipes adapted to receive the discharged vapor and lead it into the mixing-chambers, concentric cups are exactly movable relative to each other said cups including the jet-nozzles and the mouths of the receiving-pipes, and having perforations to be moved into and out of line and through which air is admitted and delivered with the vapor into the mixing-chambers, and pipes leading from the mixing-chambers to each of the burners.

699,913. AUTOMATIC PRINTING-PRESS CONTROLLER. T. M. DE VERA, New York, N. Y. Filed May 21, 1901. Serial No. 61,602. (No model.)

Claim.—1. In combination with a printing-press and feeder, the automatic stop mechanism, a tripper controlling said stop mechanism, and a detent movable to and from a position to restrain the action of the tripper, two disks disposed side by side and oscillating independently of each other, means for transmitting motion from one of said disks to the other, a guard carried on the other of said disks to and from a position to prevent transmission of motion to the detent, and a feather actuated by the paper in transit to the press and controlling the motion of the guard-carrying disk.

2. The combination with a printing-press and its actuating mechanism, of a pivoted tripper-disk, a rod connected to said disk and at the opposite end to the above-said actuating mechanism to control the same, means actuating said disk to automatically arrest the actuating mechanism, a key on said disk, a latch engaging said key and restraining thereby the action of the disk, an oscillatory disk, means for transmitting motion from said disk to the latch to throw it out of engagement, a guard movable to and from a position to prevent said transmission of motion to the latch, and a feather actuated by the paper in transit to the press and controlling said guard as set forth.

3. The combination with a printing-press and its actuating mechanism, of a pivoted tripper-disk, a rod connected to said disk and at the opposite end to the above-said actuating mechanism, a movable detent normally disposed to restrain the action of said tripper, a pivoted disk provided with a pawl to engage said detent, means for throwing the detent out of restraining position by the movement of said disk, an oscillatory lever provided with a pawl to engage said detent, and a feather actuated by the paper in transit to the press and controlling said lever as set forth.

4. The combination with a printing-press, an automatic paper-supplier, a feed-board and mechanism actuating said press and supplier in common, of a pivoted tripper suitably connected to said mechanism to control the same, means actuating said tripper to arrest said mechanism, a movable detent normally disposed to restrain the action of said tripper, a pivoted disk provided with a shoulder on its periphery, an oscillatory lever provided with a pawl to engage said shoulder, means for throwing the detent out of restraining position by the movement of said disk, an oscillatory disk at the side of the shoulder-disk and provided with a guard for throwing the pawl out of engagement, mechanism imparting motion to said guard-disk, a rod-disk disposed transversely over the delivery end of the feed-board, an arm attached to said rod-disk, a rod connecting said arm to the above-said guard-disk, and a feather actuated by the paper in transit to the press and controlling said rod-disk as set forth.

699,914. CHILING-MACHINE. CHARLES W. REED, Pittsburgh, Pa. Assignor of one-half to Thomas P. Reed, Pittsburgh, Pa. Filed Aug. 10, 1901. Serial No. 74,774. (No model.)

Claim.—1. In an electric current of the class set forth, the combination of a base-block having diametrically-disposed contact-pieces comprising inwardly-extending horizontal members and outwardly-located vertically-disposed corrugated heads open at the bottom, the inwardly-extending members forming seats with adjacent portions of the block, a cover having a series of contact-strips of similar form and comprising resilient loops with depending lips over portions of the bodies thereof beneath, flexible connections interspersed between the loops and held by the lips and terminals attached to a portion of said strips, a part of the strips being arranged to engage the contact-pieces of the base-block.

2. In an electric cut-out of the class set forth, the combination with a base-block having contact devices or pieces which in part engage the main conductors, of a cover having a series of contact-strips of similar form and comprising resilient loops with depending lips over slots in the bodies thereof beneath, flexible connections interspersed between the loops and held by the lips, and terminals attached to a portion of said strips, a part of the strips being arranged to engage the contact-pieces of the base-block.

3. A contact-strip for an electric cut-out having a loop bent or extending thereover and provided with depending lips at the sides which are located over side edge strips in the body of the strip below the loop.

699,915. TATTOOING INSTRUMENT. JOHN PERRY, San Francisco, Cal. Filed Aug. 28, 1901. Serial No. 75,001. (No model.)

Claim.—1. In a tattooing instrument, the combination with two-linked levers having suitable jaws and handles; of a third link, pivotally attached to said levers and carrying a holder and tattooing device carried by said holder as shown, and specified.

2. In a tattooing instrument, the combination with two-linked levers provided with handles, and having jaws of suitable shape to fit in the mouth and held and support the nose of an animal, of a third link, pivotally attached to said two-linked levers, and provided with means for taking the nose, as specified.

699,916. BODY-BINDER. CHARLES E. CHAMBERLAIN, Burlington, Iowa. Filed Sept. 21, 1901. Serial No. 75,776. (No model.)

Claim.—1. A body-binder, comprising a block of suitable material, rods projecting therefrom, and oval-shaped rollers suitably mounted thereon, each having its periphery provided with cupping-notches, the said peripheries being of the same material of said rollers, substantially as described.

2. A body-binder, comprising a block of suitable material, rods projecting therefrom, and oval-shaped rollers suitably mounted thereon, each having its periphery provided with cupping-notches, the said peripheries being of the same material of said rollers, substantially as described.

3. A body-binder, comprising a block of suitable material, oval-shaped rollers suitably curved thereby, the peripheries of said rollers being formed of rigid material and each provided with a plurality of cupping-notches, substantially as described.

4. A body-binder, comprising a block of suitable material, rods projecting therefrom, and oval-shaped rollers suitably mounted upon said rods and provided with integral rigid peripheries each having a cupping-notch thereby, substantially as described.

699,917. BOTTLEING-MACHINE. HENRY GUTENBERG, New York, N. Y. Filed Mar. 7, 1902. Serial No. 70,104. (No model.)

Claim.—1. In a bottleing apparatus the combination of the liquid-out, the two flexible feed-tubes connected to said faucet, the bottle-stopper through which the lower end of said feed-tubes passes, the two flexible vent-tubes also passing through said stopper and of approximately equal length with the feed-tubes, and means for supporting the upper end of said vent-tubes at or about the level of the faucet, said upper end of said vent-tubes being open to the atmosphere, together with the overflow-tank having a connection with the vent-tubes above the level of the bottom of said tank.

2. In a bottleing apparatus the combination of the liquid-out, the two flexible feed-tubes connected to said faucet, the bottle-stopper through which the lower end of said feed-tubes passes, the two flexible vent-tubes also passing through said stopper and of approximately equal length with the feed-tubes, and means for supporting the upper end of said vent-tubes at or about the level of the faucet, said upper end of said vent-tubes being open to the atmosphere, together with the overflow-tank having a connection with the vent-tubes above the level of the bottom of the tank, and the additional feed-tube connected to the lower part of said overflow-tank.

3. In a bottleing apparatus, the combination of the liquid-out and faucet, the two flexible feed-tubes connected to said faucet, the bottle-stopper through which the lower end of said feed-tubes passes, the two flexible vent-tubes also passing through said stopper, and of approximately equal length with the feed-tubes, and means for supporting the upper end of said vent-tubes at or about the level of the faucet, said upper end of said

vent-tube being open to the atmosphere, together with the overflow-tank supported on the bag and having a connection with the vent-tube above the level of the bottom of said tank.

699,918. TRACE. **FRANK H. GYLLBERG**, Liberty Corner, N. J. Filed July 13, 1891. Serial No. 68,174. (No model.)

Claim.—1. A draft connection consisting of opposite pulleys, one of which is provided with an elastic fastening, and a flexible trace having its intermediate portions reeved through the opposite pulleys, one end of the trace being fixed to the other pulley and the opposite end of the trace having a fastening for engagement with the part to which the first-mentioned pulley is to be connected.

2. A draft connection, consisting of opposite pulleys, one of which is provided with angularly-related spring-fastenings for engagement with a harness-roller, and the other being constructed for connection to a draw-bar, and a flexible trace having its intermediate portions reeved through the opposite pulleys, one end of the trace being fixedly connected to the said other pulley, and the opposite end of the trace having a collar-engaging fastening.

699,919. WINDOW. **MORRIS BLUMBERG**, Brooklyn, N. Y. Filed Aug. 18, 1891. Serial No. 72,022. (No model.)

Claim.—1. In a window, and in combination with slideable bar, a window having hinged connection therewith, and a slide-block having a T-shaped leg, a brace-bar having pivotal connection at one end with the window and provided at its opposite end with an oblique opening and a round cam-bush for reception of the arm of the T-shaped leg after the latter has passed through the said oblique opening, substantially as set forth.

2. In a window, and in combination with slideable bar, and a window having hinged connection therewith, a fastening comprising complementary members secured to, respectively, the slideable bar and side stile of the window and having cooperating beveled portions, and a lock-pin applied to a side stile of the window to pass through corresponding openings in the said members of the fastening, substantially as set forth.

3. In a window, and in combination with slideable bar, and a window having hinged connection thereto, a lock-pin slideably mounted in an opening formed in a side stile of the window for receiving the latter when closed, said pin having an intermediate flattened portion, and an intermediate-plate having a keyhole-slot and secured to the side stile of the window with the flattened portion of the lock-pin arranged to operate in the notched portion of the said keyhole-slot, substantially as set forth for the purpose set forth.

4. In a window, and in combination with slideable bar having vertical slots, a window having hinged connection with the said bar so as to swing open and shut, slide-blocks having notched legs for reception of the limited end of the rope or cord leading from the counterbalance, said blocks mounted for sliding movement in the aforesaid vertical slots and having the open sides of the notches closed by a side of the said slots, and brace-bars connecting the slide-blocks with the hinged window, substantially as set forth.

5. In a window, and in combination with the element having a vertical groove, slideable bar, and a window having hinged connection with said slideable bar, a lock-pin applied to the window for cooperation with a slideable

bar to hold the window closed and adapted to enter the aforesaid groove for holding the window open without interfering with its sliding movement, substantially as set forth.

699,920. ART OF MAKING LEAF METAL. **FRANZOS HANNA**, Pasing, Germany. Filed Sept. 1, 1899. Serial No. 56,955. (No specification.)

Claim.—The improvement in the art of beating gold and other metals into leaf metal, which consists in assembling the sheets of metal, for the final beating, with sheets of "Purpura," or substantially similar paper, and then beating the sheets so assembled in the usual manner.

699,921. HYDRAULIC CUTTING MACHINE. **STEPHEN B. KARPIS**, St. Louis, Mo., assignor of two-thirds to Edward W. Moon and Joseph M. Berry, St. Louis, Mo. Filed July 13, 1891. Serial No. 68,156. (No model.)

Claim.—1. In a small cutting machine, the combination with a punch-disk, punch carried thereby and an operating-lever, of independently-mounted retaining means arranged for engagement with the punch-disk, and means connected with the operating-lever moving the retaining means into engagement with the punch-disk in advance of the punching of the sheet.

2. In a small cutting machine, the combination with a punch-disk and punch carried thereby, of a vertically-movable retaining-pin, a transversely-movable slide-bar moving the retaining-pin positively into and out of engagement with the punch-disk, and single means for operating the punch-disk and slide-bar.

3. In a small cutting machine, the combination with a die-disk and die carried thereby, and a punch-disk and punch carried thereby, of an operating-lever, a retaining-pin arranged for engagement with said punch-disk, and a slide-bar positioned to said retaining-pin and adapted to receive the engagement of said operating-lever, substantially as described.

4. In a small cutting machine, the combination with a die-disk and die carried thereby, and a punch-disk and punch carried thereby, of an operating-lever, a retaining-pin arranged for engagement with said punch-disk, a slide-bar arranged to operate in said retaining-pin, downwardly and upwardly extending arms carried by said slide-bar, said slide-bar being adapted to receive the connection of said operating-lever to move said arms into said retaining-pin, substantially as described.

5. In a small cutting machine, the combination with a die-disk and die carried thereby, a punch-disk and punch carried thereby, plungers by which said punches are carried, of lift-bars attached to said plungers, guide-pins on which said lift-bars ride and springs surrounding said guide-pins and adapted to bear against the under side of said lift-bars, substantially as described.

6. In a small cutting machine, the combination with plungers carrying a punch and operating means for the plunger, of a lift-bar attached to said plunger, and a spring normally raising the lift-bar at one end and means carried by the plunger-operating means for raising it to the other end.

7. In a small cutting machine, the combination with a die-disk and die carried thereby, a punch-disk and punch carried thereby, a plunger by which said punches are depressed, of an operating-plunger, a steel projecting from said operating-plunger and a feeding mechanism comprising a vertical slide-bar, feed-wheels journaled to said slide-bar, a wheel-wheel and a spring-supported roller-arm carrying a pawl adapted for engagement with said wheel-wheel and arranged to receive the engagement of a steel carried by said operating-plunger, substantially as described.

699,922. FEEDING-BOARD. **ANDREW F. STONE** and **THOMAS HOGAN**, Chicago, Ill. Filed Aug. 3, 1891. Serial No. 70,100. (No model.)

Claim.—1. In an ironing-stand the combination with a suitable base, of a standard vertically adjustable on said base, a casing constructed to contain heating and cooling devices carried by said standard, an heating-board hinged to said casing, and means for adjusting said standard.

2. In an ironing-stand, the combination with a suitable base, of a standard vertically adjustable on said base, the casing carried by said standard, brackets hinged to said casing, an heating-board adjustable vertically relatively to said brackets, and means for adjusting said standard and heating-board.

3. The combination with an ironing-stand, of a cooling-tank, a suitable support movable vertically into and out of said tank, a lever to which said support is connected, said lever being pivoted to the stand and a spring arranged to normally hold the lever and support in their elevated position.

4. In an ironing-stand, the combination with a base, of a standard adjustable relatively to said base, a casing carried by said standard and constructed to contain heating and cooling devices, an heating-board hinged to said casing, and means for adjusting said parts relatively to the base comprising a rack secured to the standard, a pinion journaled in the base, a hand-wheel for operating said pinion and a rack and pawl arranged to prevent the backward rotation of the pinion.

5. In an ironing-stand, the combination with the brackets hinged to a suitable support, of a hand vertically adjustable relatively to said brackets and means for adjusting said hand comprising a rack secured to the board, a pinion shaft journaled in the brackets, a pinion upon said shaft engaging the rack, a hand-wheel for turning said shaft and a pawl and ratchet adapted to prevent the backward rotation of the shaft.

6. In an ironing-stand, the combination with the standard and the casing, of the brackets pivoted to said casing, the heating-board secured to said brackets, a door adapted to close one end of the casing and a hinge-pin upon which said door is hinged, said pin having its opposite ends projecting through the casing and forming stops for the brackets.

7. The combination with a laundry-board having a series of uniformly-projecting pins extending around its edges and adapted to engage the edges of the cover, of a removable guard, V-shaped in cross-section and comprising two pivotally-connected parts extending around the board over said pins, the free ends of said guard being adjustably secured together.

699,923. SPACING DEVICE. **CHARLES C. LAM**, Boston, Mass. Filed Dec. 18, 1891. Serial No. 71,124. (No model.)

Claim.—1. A spacing device consisting essentially of a horizontal rack, a carrier adapted to be moved thereon, means for locking the carrier against backward movement, a vertical rack rigidly secured to the horizontal rack and means for locking the vertical rack and the carrier against downward movement.

2. A spacing device consisting essentially of a horizontal rack, a carrier adapted to be moved thereon, a double-acting pawl for locking the carrier against backward movement, a vertical rack rigidly secured to the horizontal rack and a pawl for locking the vertical rack and the carrier against downward movement.

3. A spacing device consisting essentially of a frame, a horizontal rack, a carrier adapted to be moved thereon, a pawl for locking the carrier against backward movement, a vertical rack rigidly secured to the horizontal rack and a pawl carried by the frame and adapted to engage the vertical rack to lock the latter and the carrier against downward movement.

4. A spacing device consisting essentially of a frame, a horizontal rack, a carrier adapted to be moved thereon, a pawl for locking the carrier against backward movement, vertical racks rigidly secured to the horizontal rack and an oscillating shaft mounted on the framework and carrying pawls adapted to engage the vertical racks.

5. A spacing device consisting essentially of a frame, a horizontal rack, a carrier adapted to be moved thereon, a pawl for locking the carrier against backward movement, vertical racks rigidly secured to the horizontal rack, an oscillating shaft mounted upon the framework and pawls rigidly secured to the shaft and carrying engaging projections at opposite ends, so that the racks and the carrier may be depressed and may be locked by the pawls against further downward movement.

6. A spacing device comprising a horizontal rack, a carrier adapted to be moved thereon, means for locking the carrier against backward movement, a vertical rack rigidly secured to the horizontal rack, an oscillating shaft, pawls carried by said shaft and having upper and lower legs adapted to engage the vertical rack, the teeth of the racks and the engaging legs bearing such a relation to each other that said legs cannot be out of the engaging position simultaneously, so that on oscillation of the shaft will permit the vertical rack and carrier to drop one tooth in two distinct movements.

699,924. STATION-INDICATOR. **FRANK C. LAMONT**, Chicago, Ill. Filed Oct. 21, 1891. Serial No. 71,476. (No model.)

Claim.—1. In a station-indicator, a casing, an endless strip or band contained therein and bearing the names of the stations, there being in the opposite edges of said strip equidistant openings, a pair of feed-rollers between which said strip is guided, one of said rollers having teeth for the engagement of the openings in the strip, and the opposite rollers having openings to receive said teeth, and mechanism for actuating said rollers.

2. In a station-indicator, the combination of the casing or casing, an endless strip or band bearing the names of the stations, there being in the opposite edges of said strip openings for the reception of feeding-teeth, a pair of feeding-rollers arranged in the lower portion of the casing and having a series of smaller grooves, one of said rollers being provided with teeth for engagement in the strip-openings, means for operating said rollers, guards having fingers being in opposite directions and adapted to the spiral grooves in the rollers, strip-guiding devices arranged at the upper portion of the casing, and a tension-bar adapted to engage with the strip in advance of the exposure-point.

3. In a device of the class described, a pair of feeding-rollers to

twice which the station-indicating strip or ball is guided and fed, an adjustable block arranged in contact with one of said rollers, a spring normally acting on the opposite end of said block, and means for adjusting said spring to increase or decrease the pressure of the feeding-roller, substantially as described.

4. In a station-indicator, an indicating-strip, a feeding-roller therefor, and mechanism for operating said feeding-roller, said mechanism comprising a gear-wheel mounted loosely on a shaft and operatively connected to a pinion on the shaft of the feed-roller, a ring having recessed inner and outer faces secured to one side of said gear-wheel, a locking-dog adapted to engage in one of the outer recesses, a disk, a pawl thereon adapted to engage with one of the inner recesses of the ring, and mechanism for unlatching the ring and for rotating said disk and ring, substantially as specified.

5. In a station-indicating mechanism, the combination with indicating mechanism, of feeding device comprising a stationary shaft, a primary gear mounted loosely thereon, a ring secured to one side of said gear-wheel and having recesses in its inner and outer faces, a dog adapted for locking engagement in the outer recesses, a pivoted lever carrying said dog, an arm pivoted to said lever, a cam carried by said arm, a disk also mounted loosely on the shaft, a pawl carried by the disk for engagement in the inner recesses of said ring, a rope wheel also mounted loosely on the shaft, a spring connecting said wheel to said disk, a return-spring connecting the wheel to the stationary shaft, and a pin carried by said wheel for engagement with said cam, substantially as described.

6. In a station-indicator, the combination with the indicating device, of an actuating mechanism comprising a wheel having a fixed limit of relative movement, an operating-wheel having a variable movement, and a yielding connection between said operating-wheel and said first-named wheel, substantially as described.

7. In a station-indicating mechanism, the combination with indicating device, of a primary wheel adapted to receive a relative movement of variable extent, a second wheel connected to the indicating device and having a fixed predetermined limit of movement, means for releasing and locking said second wheel, and a yielding connection between the two wheels, substantially as described.

8. In a station-indicator, an indicating device, an operating-lever pivoted under the car and adapted for yielding operative engagement in both directions with a series of projections on the roadway, an opening rope or chain extending between the upper end of said lever and the indicating mechanism, a vertically-disposed spring connecting the upper end of said lever to a fixed point, and guiding-rollers situated one on either side of the vertical center of the lever and adapted to receive and guide the rope or chain.

699,995. CATTLE-GUARD. EDGAR T. HERRON, CHICAGO, ILL. Filed Feb. 12, 1908. Serial No. 94,678. (No model.)

Claim.—A cattle-guard comprising the central and side sections, and the side wings consisting of upright frames of angle-iron tapered toward the mid sections and provided at the top and lower end with open or pointed, barbed wires, and braces supporting the barbed wires and the frames, substantially as described.

699,996

699,996. NUT-LOCK. EDWARD E. HERRON, ST. LOUIS, MO. Filed Jan. 6, 1908. Serial No. 95,000. (No model.)

Claim.—The combination with a notched threaded member, of a nut provided with a groove in the face thereof, a tongue constructed of spring material, carried by said nut and adapted to enter said groove to engage the notch in said threaded member, and a guard carried by said nut arranged to receive the free end of said tongue, substantially as described.

699,997. TROLLEY. FREDERICK M. HERRON, TROBROOK, LIVERPOOL, ENGLAND. Filed June 26, 1906. Serial No. 95,051. (No model.)

Claim.—1. A trolley-head having a fork in which the trolley is mounted, the said fork being removably secured on the end of a trolley-pole, means for securing the end of a conducting-wire at the end of the trolley-pole, means for insulating the trolley-head from the said trolley-pole, and a contact-plate carried by the trolley-head for engaging the means employed for securing the end of the conducting-wire in the trolley-pole, substantially as described.

2. In a trolley-head, the combination with a pole having a conducting-wire passing through the same, means for insulating the end of the wire from the end of the pole, the said trolley-head having a contact for fitting around the end of the pole, and means for insulating said contact from said pole, a contact-piece secured upon the end of the pole to the conducting-wire, and a contact-plate in the said contact for engaging the same, substantially as described.

3. In a trolley-head, the arrangement for enabling the trolley-head to separate from the pole without injury to the conducting-wire when an exceptional pull is applied, namely passing the conducting-wire through the pole and at the end fastening it to an outer metallic contact-plate insulated or not as required from the pole but in electrical contact with the trolley-head, and making a split in the trolley-head whereby it can be compressed around the trolley-pole, substantially as described.

4. A trolley-head having a longitudinal split therein, legs with a clamping-bolt for compressing the contact around the trolley-pole, a recess or channel at the end of the contact, in combination with a corresponding

leg further or projection on the pole which enters the channel and prevents the head from turning when actuated on the pole, substantially as described.

5. In a trolley, the combination with the trolley-pole of an outer metallic contact-plate insulated therefrom to which the wire is secured, and a socket on the trolley-head clamped around said plate with sufficient grip to prevent them separating under ordinary conditions, substantially as described.

6. In a trolley, the combination with a trolley-pole and a contact secured to the free end thereof, of a trolley-head having a depending spindle arranged at right angles to said contact and engaging a bearing in the end thereof, the said spindle projecting beyond said bearing, an arm secured to the end of said spindle, and a spring connecting the arm with said contact for the spring exerting a straight pull on said arm holding the trolley-head in proper alignment therewith, under yielding pressure, substantially as described.

7. In a trolley, the combination with a trolley-pole of a trolley-head formed with a socket adapted to fit upon the end of the pole, clamping means on said head for gripping the end of the pole, a fork carrying the trolley, the said fork being hinged to the rear of the said socket, a spindle attached to the said fork, an arm carried by the said spindle, and a spring connecting the arm with the projection on the trolley-head, so that the fork is normally held in alignment with the trolley-wire under yielding pressure, the spring and means for holding the said fork in position remaining with the trolley-head whenever the same is separated from the pole, substantially as described.

699,998. WIRE VENTILATOR. CHARLES McVINTY and JOHN F. PARR, PHILADELPHIA, PA. Filed July 14, 1907. Serial No. 95,114. (No model.)

Claim.—1. A ventilator comprising in combination with a series of curved plates of gradually-increasing width having tapered edges form-

ing grooves, a series of split tubes or ribs for engaging the grooves of said plates, and ribs arranged at the base and mouth having grooves engaging the plates and openings to receive the ribs substantially as specified.

2. A ventilator comprising a curved tapered plate arranged in cross-section composed of plates A, having tapered and flaring grooves, the B in the form of split tubes for engaging and holding said plates in position, and ribs C and D arranged respectively at the base and mouth of the ventilator having slotted openings to receive the plates and openings for the ribs, substantially as specified.

699,999. WINDER-GUARD-CLIPPER-BRAKE-DRUM. JAMES T. W. KENNEDY, ST. LOUIS, MO., assignor to KENNEDY BRAKE DRUM COMPANY, ST. LOUIS, MO., a Corporation. Filed Oct. 21, 1907. Serial No. 79,388. (No model.)

Claim.—1. The combination of a brake-beam, a clip fitted against the beam and having an arm extending rearwardly therefrom and resting on the body of the beam, an eyebolt for connecting the arm to the beam, and a finger-guard fitting in a socket formed in the clip and the lower end of which bears against the beam, substantially as set forth.

2. A brake-beam having a flange and a web, a clip fitted against the face of the flange and having an arm passing over the upper edge of the flange and seated upon said web, and having a clip fitting beneath the lower edge of the flange, an eyebolt connecting the arm of the clip to the web of the beam, and a finger-guard fitting in a socket formed in the clip and the lower end of which is provided with a head that bears against the face of the flange of the beam, substantially as set forth.

699,980. KNITTING-MACHINE. WILLIAM E. HERRON, TROBROOK, ENGLAND. Filed June 11, 1907. Serial No. 95,105. (No model.)

Claim.—1. In a straight-knitting machine for knitting ribbed work, a set of substantially horizontal and a set of substantially vertical needles, means to actuate the vertical needles, means to impart a preliminary forward movement to said horizontal needles and then substantially arrest them with their free ends back of the rear sides of the vertical needles to thereby sufficiently slacken the tension on the loops held by both sets of said needles, a knock-off bar, and means to actuate it while the horizontal needles are substantially arrested to meet and knock over from the cheeks of the vertical needles the loops next to be cast off to the knitting.

2. In a straight-knitting machine for knitting ribbed work, two sets of bearded needles, one set being arranged substantially vertical and the other substantially horizontal, means to actuate the vertical needles, means to impart a preliminary forward movement to said horizontal needles and then substantially arrest them with the ends of the beards back of the rear sides of the vertical needles to thereby slacken the tension on the loops held by both sets of said needles, a knock-off bar, and means to actuate it while the horizontal needles are in position to slacken the loops pulling the outer edge of said knock-off bar in or above the plane of movement of the rear sides of the horizontal needles.

3. In a machine of the class described, a series of vertical needles, means to actuate them, a needle-bar having an attached series of horizontal needles, means for moving said horizontal needles forwardly, actuating-levers coacting with the bar carrying said horizontal needles, and a cam having a depression to enable the bar carrying said horizontal needles to provide of a preliminary forward movement and then arrest said bar with the ends of the horizontal needles near the rear sides of the vertical needles, to thereby slacken the tension on the loops extended from one to the other set of said needles preparatory to knocking off the loops held on the cheeks of the vertical needles.

4. In a machine of the class described, a series of vertical needles, means to actuate them, a knock-off bar coacting with the vertical-needles,

699,981. AUTOMATIC ATTACHMENT FOR PIANOS. JOHN A. SARRIS, Baltimore, Md., assignor to Smith Lyngbush Company, a Corporation of West Virginia. Filed May 10, 1901. Serial No. 99,000. (No model.)

Claim.—1. In an automatic attachment for pianos, the combination of the two stationary ends of the casing; a metal frame, carrying the operative parts of the instrument, having legs projecting at right angles thereto and extending into said ends; means passing through the said legs and ends for vertically adjusting the frame with relation to said ends, substantially as described.

2. In an automatic attachment for pianos, the combination of the two stationary ends of the casing each having a vertical hole passing down from the top thereof; a metal frame, carrying the operative parts of the instrument, having legs projecting at right angles thereto and extending into the said ends; and a bolt passing through the vertical hole in the said ends and through the legs, for vertically adjusting the frame with relation to the said ends, substantially as described.

3. In an automatic attachment for pianos the combination of a frame adjustably secured to the ends of the casing and carrying the operative parts of the instrument; means to raise and lower the frame; a driving-shaft; belt connecting the driving-shaft with the treadle; treadle having blocks on their under side secured thereto by screws for gripping said belt, and open through which said belt pass, as and for the purpose described.

4. In an automatic attachment for pianos, the combination of a frame secured to the ends thereof and carrying the operative parts of the instrument; a belt to raise and lower the frame; a driving-shaft; belt connecting the treadle with the driving-shaft; and means to adjust the said treadle with relation to the said belt, to maintain the proper angle of the said treadle, as and for the purpose described.

699,982. PROCESS OF PURIFYING FLUID SUGAR-WEARING MATERIAL. CLARENCE A. SWINBERG and CLARENCE A. KERR, New York, N. Y., assignors to Federal Refining Company, Jersey City, N. J., a Corporation of New Jersey. Filed Nov. 13, 1901. Serial No. 99,001. (No model.)

Claim.—1. A device of the class described comprising a seat, a leg pivotally connected at a point between its ends with the seat and adapted to be arranged at different angles, and means for detachably connecting the upper end of the leg with the seat, whereby the leg is rigidly held in its adjusted position, substantially as described.

2. A device of the class described comprising a seat, a leg pivotally and elastically connected at a point between its ends with the seat and adapted to be arranged at different angles, and means for detachably interlocking the upper end of the leg with the seat, whereby when the leg is drawn outward, it will be disengaged from the seat, and when moved inward will be engaged with the seat, substantially as described.

3. A device of the class described comprising a seat provided at opposite sides with arms, a belt having the arms pivotally connected to it, a sliding leg pivotally connected with the seat, and means for connecting the leg to the belt, whereby the leg and the seat are retained in their adjusted position, substantially as described.

4. A device of the class described comprising a seat designed to be connected to a person, and a sliding leg pivotally and elastically connected near one end with the seat and adapted to be arranged at different angles and having an interlocking connection with the seat, whereby it is held rigidly with the seat, substantially as described.

5. A device of the class described comprising a seat, a sliding leg

pivotally connected between its ends with the seat and interlocked with the seat, said leg being capable of a limited longitudinal movement, whereby it is engaged with and disengaged from the seat, and a fastening device for holding the leg against such longitudinal movement, substantially as and for the purpose described.

6. A device of the class described comprising a seat designed to be connected to and carried by a person, a leg provided at its upper end with teeth and having a slot, a pivot carried by the seat and connected with the same and arranged in the said slot, and means carried by the seat and cooperating with the teeth of the leg, whereby the seat and the leg are interlocked, substantially as described.

7. A device of the class described comprising a seat provided with arms, a leg having a slot and arranged between the arms and provided with recesses, inner and outer fastening devices carried by the arms, the outer fastening device being arranged in the slot of the leg and the inner fastening device being arranged to fit in the said recesses, a key adapted to lock the leg against movement, and means for causing the seat to be a person, substantially as described.

699,983. PROCESS OF PURIFYING FLUID SUGAR-WEARING MATERIAL. CLARENCE A. SWINBERG and CLARENCE A. KERR, New York, N. Y., assignors to Federal Refining Company, Jersey City, N. J., a Corporation of New Jersey. Filed Nov. 13, 1901. Serial No. 99,002. (No model.)

Claim.—1. The process of treatment of sugar, which consists in mixing with a sugar solution a defecating or clarifying liquid containing a sulfonated body and then separating said liquid and the impurities from the solution, substantially as described.

2. The process of treatment of sugar, which consists in mixing with a sugar solution a sulfonated body, and then separating the sulfonated body and impurities from the solution, substantially as described.

3. The process of treatment of sugar, which consists in mixing with a sugar solution a sulfonated body, and then separating the sulfonated body and impurities from the solution, substantially as described.

4. The process of treatment of sugar, which consists in mixing with a sugar solution a sulfonated derivative of a resinous body, and then separating said derivative and the impurities from the solution, substantially as described.

699,984. BRASS. BENJAMIN SWINBERG, Chicago, Ill. Filed Feb. 17, 1901. Serial No. 99,003. (No model.)

Claim.—1. An error in which is combined a handle, a revolvable screw-disk mounted in a bearing at one end thereof, the axis of which is arranged at right angles to that of said handle, a spring secured to the opposite end of said handle, a pulley upon the axis of said disk and a cord trained over said pulley, one end of which is attached to said spring, and the other of which is free to be grasped by the hand.

2. An error in which is combined a tubular handle, a revolvable screw-disk mounted thereon, a spiral spring within said handle, cords having their ends attached to said spring and said handle being trained over pulleys upon opposite sides of said disk, and a handle attached to the opposite ends of said cords, substantially as and for the purpose specified.

legs upon opposite sides of said disk, and a handle attached to the opposite ends of said cords, substantially as and for the purpose specified.

699,985. COTTON-PRESS. AMER R. TUCKER, Little Rock, Ark., assignor to Thomas C. Thompson Company, a Corporation of Arkansas. Filed Sept. 14, 1901. Serial No. 75,573. (No model.)

Claim.—1. In a cotton-press, the combination of a bale-forming mechanism, device for raising upon the top layer of cotton to depress the same after the formation of the bale, and means for holding the top layer of cotton in each depressed position as the bale is transferred from the bale-forming mechanism.

2. In a cotton-press, the combination of a preliminary-bale-forming mechanism, a finishing mechanism, device for raising upon the top of the bale to depress the same after the formation of the latter, and means for holding the top of the bale in each depressed position as the bale is transferred from the preliminary-bale-forming mechanism to the finishing mechanism.

3. In a cotton-press, the combination of a bale-forming mechanism, means adapted to be inserted between the bale-forming mechanism and top of the bale after the formation of the latter for holding the cotton in position in the bale, and a depressor for forcing said means upon the top of the bale prior to removal from the press.

4. In a cotton-press, the combination of a bale-forming mechanism, means adapted to be inserted between the bale-forming mechanism and top of the bale after the formation of the latter for holding the cotton in position in the bale, a depressor for forcing said means upon the top of the bale prior to removal from the press, and device for holding said means in depressed position as the bale is moved from the bale-forming mechanism.

5. In a cotton-press, the combination of a preliminary-bale-forming mechanism, a finishing mechanism, and means adapted for insertion between the preliminary-bale-forming mechanism and the top of the bale after the formation of the latter for holding the layers of cotton in position as the bale is transferred from under the preliminary-bale-forming mechanism, and device for depressing said means upon the top layer of cotton prior to the removal of the bale from the press.

6. In a cotton-press, the combination of a bale-forming mechanism for laying cotton layer upon layer in the formation of a bale and maintaining the same under compression during the formation thereof, device operative upon the top of the bale to depress the same after the formation of the bale, and means for holding the top of the bale in each depressed position as the bale is transferred from the bale-forming mechanism.

7. In a cotton-press, the combination of a traveling carriage, two series of rollers mounted thereon to travel therewith, an endless belt or apron passing around each series of rollers to form a hopper or receptacle for cotton and feed the same between them, a set of rollers mounted on said carriage below the said belt or apron and a curved set of rollers mounted below said first-mentioned set, and means for driving the second set of rollers at an increased speed to draw out the fibers of the top.

8. In a cotton-press, the combination with a preliminary-bale-forming mechanism, a finishing mechanism, means adapted to be inserted between the preliminary-bale-forming mechanism and top of the bale after the formation of the latter for holding the cotton in proper position in the bale as the latter is transferred from the preliminary-bale-forming to the finishing mechanism, and device for forcing said means against the top of the bale after the said means has been inserted as specified.

9. In a cotton-press, the combination with a preliminary-bale-forming mechanism, a finishing mechanism, means adapted to be inserted between the preliminary-bale-forming mechanism and top of the bale after the formation of the latter for holding the cotton in proper position in the bale as the latter is transferred from the preliminary-bale-forming to the finishing mechanism, and device for forcing said means against the top of the bale after the said means has been inserted as specified, and instrumentalities for maintaining the said means in position on the bale as it is transferred from one mechanism to the other.

10. In a cotton-press, the combination of a baling box or chamber, a hopper, means for representing one of said parts with respect to the other to lay layers of cotton upon each other in the formation of a bale, a pressure device to maintain pressure upon the cotton as it is laid layer upon layer, device for raising upon the top layer of cotton to depress the same after the formation of the bale, and means for holding the top layer of cotton in each depressed position as the bale is removed from the press.

11. In a cotton-press, the combination of a baling box or chamber and a bale-forming mechanism, means to move one of said parts with respect to the other to lay the top layer upon layer in the formation of a bale, pressure device for exerting pressure upon the bale as it is formed, belt for opposing the pressure device, a cut-off adapted to be inserted over the top of the bale after the formation thereof and means passing through suitable passages in one of said belts for forcing the cut-off upon the top of the bale.

12. In a cotton-press, a preliminary-bale-forming mechanism comprising two series of rollers to feed a top-of cotton layer upon layer in the formation of a bale, a pressure device for maintaining the layers of cotton pressed against said rollers as the bale is being formed, in combination with a cut-off adapted to be inserted over the top of the bale after the formation thereof, means passing through suitable passages in one of said belts for forcing the cut-off upon the top of the bale and device for maintaining the cut-off in position on the bale as the latter is removed from the press.

13. In a cotton-press, the combination of a hopper, a series of rollers at each side thereof, a plurality of belts carried by one of said series of rollers with a space between them, a cut-off, and a cut-off depressor movable in the space between the belts.

14. In a cotton-press, the combination of a hopper, a series of rollers at each side thereof, a belt-carried by one of the said series of rollers, a plurality of belts carried by the other series of rollers with a space between them, a cut-off adapted to be inserted between the said plurality of belts, and a cut-off depressor movable in the space between the belts.

15. In a cotton-press, the combination of a hopper, a series of rollers at each side thereof, a plurality of belts carried by one of said series of rollers with a space between them, and a cut-off depressor com-

prising handle-bar, and push-bar operable therefrom, said push-bar passing between said belt, and a cut-off adapted to be inserted in the space between the belt and to be engaged by the push-bar.

16. In a cotton-press, the combination of a carriage, a hopper mounted thereon and adapted to receive loose cotton direct from a gin or suitable source of supply, series of rollers and bale-forming surfaces mounted on said carriage, means for reciprocating said carriage to lay the cotton layer upon layer in the formation of a bale, the bale-forming surface on one of said series of rollers consisting of several parts spaced apart, a cut-off adapted to be inserted in the space between the parts of said bale-forming surface, and a cut-off depresser operable between said parts upon the cut-off.

17. In a cotton-press, the combination of a hopper, a series of rollers on adjacent ends thereof carrying bale-forming surfaces, the bale-forming surface on one of said series of rollers comprising a plurality of spaced parts, a cut-off depresser operable between the said parts of the bale-forming surface, a cut-off adapted to be inserted in the space between said parts and to be engaged by the cut-off depresser, and retaining device for holding the cut-off in place upon the top of the bale.

18. In a cotton-press, the combination of a hopper, a series of rollers on adjacent ends thereof carrying bale-forming surfaces, the bale-forming surface on one of said series of rollers comprising a plurality of spaced parts, a cut-off depresser operable between the said parts of the bale-forming surface, a cut-off adapted to be inserted in the space between said parts and having spaced ends and adapted to be engaged by the cut-off depresser, and retaining device for holding the cut-off in place upon the top of the bale.

19. A cut-off for holding the cotton in a cotton-bale as the latter is removed from the bale-forming mechanism, said cut-off comprising a series of parallel bars adapted to be placed above the bale after the formation of the latter, said parallel bars being free at one end, and a cross-piece connecting said parallel bars at the opposite end.

20. A cut-off for holding the cotton in a cotton-bale comprising a series of parallel bars, a cross-piece for connecting the bars at one end thereof, said bars being free at their opposite ends, in combination with a bale box or chamber and means carried by said box or chamber for engagement with said cut-off.

21. A cut-off for holding the cotton in a cotton-bale comprising a series of parallel bars, a cross-piece for connecting the bars at one end thereof, in combination with a bale box or chamber, hooks carried by said box or chamber for engagement with the cut-off, and means for forcing said hooks and the engaged cut-off toward the top of the bale box or chamber.

22. In a cotton-press, a bale-forming mechanism comprising a bale-box and means for laying the cotton layer upon layer in said box to form a square bale, and pressure device maintaining the layers of cotton under compression as the bale is being formed, said device comprising a plunger movable within the bale-box in combination with a differential balancing device having gearing connection with said plunger for maintaining the pressure exerted by the plunger on the layers of cotton in the bale-box uniform and equal throughout the formation of the bale.

23. In a cotton-press, the combination of a preliminary-bale-forming mechanism comprising device for supporting the bale as it is formed, bale-forming surface, means for moving one of said parts with relation to the other to lay the cotton in layers and starting-dogs mounted to the bale-forming surface to start the lay in the backward fold at the commencement of each movement.

24. In a cotton-press, a bale box or chamber, a traveling carriage, a hopper, a series of rollers and belt mounted on said carriage, means for moving the carriage back and forth over the bale box or chamber, and starting-dogs secured to the said belt.

25. In a cotton-press, the combination of bale-forming mechanism, means for maintaining the bale under desired compression as the cotton is laid layer upon layer, a follower, and automatically-engaging hooks for holding the follower in position during the laying of some of the preliminary layers and for them to automatically release said follower as the compression means act to compress the layers of cotton.

26. In a cotton-press, the combination of bale-forming mechanism comprising means for laying the cotton layer upon layer, a pressure device for maintaining pressure on the bale as it is formed, a follower and automatically-disengaging hooks for holding the follower in position during the formation of the first part of the bale and for automatically releasing the follower as the pressure device operates to apply pressure to the bale.

699,986. BALEING-MACHINE. ARTHUR B. THOMAS, Little Rock, Ark., assignor to Thomas Gin-Compress Company, a Corporation of Arkansas. Filed Feb. 16, 1902. Serial No. 94,168. (No model.)

Claim.—1. In a baling-machine, the combination of a charging-chamber, a bale-box adapted to be moved beneath said charging-chamber,

bar, and means for closing the bottom of the charging-chamber as desired to prevent material to be fed therinto while the bars are being changed.

2. In a baling-machine, the combination of a charging-chamber, a trumper or plunger movable into said charging-chamber, a bale-box adapted to be moved beneath said chamber, and means for closing the bottom of the charging-chamber as desired to prevent material to be fed therinto while the bars are being changed.

3. In a baling-machine, the combination of a charging-chamber adapted to receive material to be baled, a trumper or plunger movable into said charging-chamber, means for preventing the material from entering said charging-chamber above said trumper head or plunger, a bale-box adapted to be moved beneath said charging-chamber, and a movable bottom for said charging-chamber to permit material to be fed therinto while the bars are being changed.

4. In a baling-machine having movable baling-bars, the combination of a charging-chamber open at its upper and lower ends, a reciprocating trumper or plunger movable in said chamber and out of the upper end thereof to a position above said chamber, means for delivering material into said chamber, and means detachably connected with the trumper or plunger for cutting off the supply of material to the charging-chamber when said trumper or plunger enters said chamber.

5. In a baling-machine, the combination of a charging-chamber, a bale-box adapted to be placed beneath the said chamber, means for delivering material direct from the gin or container into said charging-chamber, a trumper or plunger movable into said chamber to transfer the material into the bale-box, a cut-off for stopping the delivery of material into the charging-chamber while the trumper or plunger is operating therein, and means for detachably connecting the cut-off and trumper or plunger to cause the former to move with the latter during the portion of its travel above the charging-chamber.

6. In a baling-machine, the combination of a charging-chamber, means for delivering material into said chamber, a trumper or plunger and means for moving it into said charging-chamber, a cut-off for stopping the delivery of material into the charging-chamber while the trumper or plunger is operating therein, and means for detachably connecting the trumper or plunger and said cut-off whereby the delivery of material to the charging-chamber may remain uninterrupted while the trumper or plunger is raised above the said chamber.

7. In a baling-machine, the combination of a charging-chamber, bale-bars adapted to be moved beneath the charging-chamber, and means for retaining material in the charging-chamber during the change of bars beneath said chamber.

8. In a baling-machine, the combination of a charging-chamber having a movable side, bale-bars adapted to be moved beneath the charging-chamber, and means for moving the side into a position to increase the capacity of the charging-chamber as the bars are changed beneath the said chamber.

9. In a baling-machine, the combination of a charging-chamber hav-

ing a movable side and bottom, bale-bars adapted to be moved beneath the charging-chamber and means for moving the side into a position to increase the capacity of the charging-chamber and to close the bottom thereof.

10. In a baling-machine, the combination of a charging-chamber for receiving material to be baled and having a hinged side and movable bottom, bale-bars adapted to be moved beneath said charging-chamber, a trumper or plunger, means for moving it into and out of said chamber, and means for turning the side of the charging-chamber open its hinges and closing the bottom of said chamber as the bars are changed beneath the chamber, whereby supply of material to said chamber need not be interrupted.

11. In a baling-machine, the combination of a charging-chamber for receiving material to be baled direct from the gin or container, said chamber having a hinged side and movable bottom, a link connecting said side and bottom to cause simultaneous movement thereof, bale-bars movable beneath the charging-chamber and operating means for said link, whereby the capacity of the charging-chamber may be increased and its bottom closed while the bars are changed beneath said chamber to permit a continuous supply of material to be received into the chamber.

12. In a baling-machine, the combination of bale-forming mechanism, a bale-box adapted to be moved beneath said baling mechanism and means interposed between the baling mechanism and bale-box for receiving and holding material to be baled during the change of bale-bars beneath said means to thereby permit the continuous operation of the supplying means.

699,987. COTTON-PRESS. ARTHUR B. THOMAS, Little Rock, Ark., assignor to Thomas Gin-Compress Company, a Corporation of Arkansas. Filed Feb. 16, 1902. Serial No. 94,168. (No model.)

Claim.—1. In a baling-machine, the combination of bale-forming mechanism, a bale-box adapted to be placed below said mechanism, and means journaled upon the bale-box and movable into position between the bale-forming mechanism and top of the bale after the formation of the latter to press the top layers of the bale away from the bale-forming mechanism and hold the material of the bale in position as the bale is moved from the bale-forming mechanism.

2. In a baling-machine, the combination of bale-forming mechanism, a bale-box for receiving the material delivered therinto from the bale-forming mechanism, device journaled upon the bale-box and movable into the top of the bale after the formation of the latter, and means for turning and continuously compressing said device upon the top of the bale to compress the layers of material below the bale-forming mechanism and retain them in such position as the bale is removed from the bale-forming mechanism.

3. In a baling-machine, the combination of bale-forming mechanism, a bale-box for receiving material to be baled, bale-holding dogs journaled upon the bale-box and movable into the top of the bale after the formation of the latter and prior to its removal from the bale-forming mechanism, and means for forcing the dogs upon the top of the bale to carry the layers of material away from the bale-forming mechanism and

holding them in such position as the bale is removed from the bale-forming mechanism.

4. In a baling-machine, the combination of bale-forming mechanism, a bale-box for receiving material to be baled, a shaft mounted on said bale-box, bale-holding dogs secured to said shaft, and means for turning said shaft to carry the dogs onto the top of the bale after the formation of the latter.

5. In a baling-machine, the combination of bale-forming mechanism, a bale-box for receiving material to be baled and having side thereon, a shaft mounted on said bale-box and carrying bale holding dogs, means for turning said shaft to carry the dogs onto the top of the bale and device for holding the dogs in position on top of the bale as the bale is removed from the bale-forming mechanism.

6. In a baling-machine, the combination of bale-forming mechanism, a bale-box for receiving the material to be baled, means for maintaining pressure on the material as it is being baled and device operated by the pressure of said means upon the material being baled for indicating the pressure on the material throughout the baling operation.

7. In a baling-machine, bale-forming mechanism comprising rollers and belt, a bale-box for receiving the material to be baled, means for maintaining pressure on the material during the baling operation, one of the rollers of the bale-forming mechanism being yielding and means connected with said yielding roller to indicate the pressure exerted on the material throughout the baling operation.

8. In a baling-machine, a pivoted bale-holding dog, said dog comprising a plurality of parts between the pivot and end thereof, said parts being flexibly united.

9. In a baling-machine, the combination of a bale-box, means for forming material into a bale, and bale-holding dogs pivotally connected to said bale-box and formed of a plurality of flexibly-united parts, said dogs movable into position upon the top of the bale after the formation of the latter for holding the layers of material in position as the bale is transferred from the bale-forming mechanism.

699,988. HEATING ATTACHMENT FOR LAMPS OR GAS BURNERS. REUBEN H. THOMAS, Chicago, Ill. Filed June 10, 1901. Serial No. 94,169. (No model.)

Claim.—1. A heating attachment for burners, comprising a rigid base-plate, a vertical supporting-arm carried thereby, and means carried by the upper end of said arm to hold the article to be heated and to guard the handle or similar portion of said article from the influence of the heat.

2. A heating attachment for lamps and the like comprising a rigid base-plate, a vertical arm or support carried thereby, a spigot carried by said arm and having a central opening, and a removable deflecting-plate carried by said spigot, said plate having a centrally-disposed perforated base adapted to said spigot-opening, substantially as specified.

699,989. ADJUSTABLE BURN AND HEAT. CHARLES E. WOOD, High, Ill., assignor to Woodruff & Edwards Company, High, Ill., a Corporation of Illinois. Filed Nov. 14, 1901. Serial No. 94,170. (No model.)

Claim.—1. In combination with a divided standard or upright for desks and seats, consisting of a movable section and a fixed section, of a threaded stem or screw operating in free contact with both sections of the standard or support, a traveling nut mounted thereon, legs or steps

on the movable section or division of the standard or support on each side of and in engagement with the traveling nut, a gear connection for turning the threaded stem or screw and actuating the traveling nut, and a cap having therein a longitudinal recess forming a guideway for the traveling nut and preventing the same from turning, substantially as described.

2. The combination of a divided standard or support for adjustable desks and seats, consisting of a movable section supported by and lying in fluid contact with a fixed section, a threaded stem or screw having thereon a traveling nut, legs or steps on the movable section or division of the standard or support in engagement with the traveling nut, a bevel-pinion on the end of the threaded stem or screw, legs on the fixed section or division furnishing a journal-bearing race for the stem or screw, a bevel-gear mounted in the fixed section or division of the standard or support and in mesh with the bevel-pinion for turning the threaded stem or screw and actuating the traveling nut, and a cap or cover provided with a recess furnishing a journal-bearing race for the stem or screw, substantially as described.

3. The combination with a divided standard or support for adjustable desks and seats, of a threaded stem or screw having thereon a traveling nut, legs or steps on the movable section or division of the standard or support on each side of and in engagement with the traveling nut, a bevel-pinion on the end of the threaded stem or screw, and a hub on the stem or screw behind the bevel-pinion, legs on the fixed section or division forming a journal-bearing race for the hub, a bevel-gear mounted in the fixed section or division of the standard or support and in mesh with the bevel-pinion, and a cap or cover attached to the fixed section or division of the standard or support including the gear and the threaded stem or screw, and having in its body a depressed journal-bearing race for the hub, substantially as described.

4. The combination with a divided standard or support for adjustable desks and seats, of a threaded stem or screw having thereon a traveling nut, legs or steps on the movable section or division of the standard or support in engagement with the traveling nut, a bevel-pinion on the end of the threaded stem or screw, a bevel-gear mounted in the fixed section or division of the standard or support and in mesh with the bevel-pinion, and a cap or cover attached to the fixed section or division of the standard or support including the gear and the threaded stem or screw and having a table or shelf forming a step for the lower end of the threaded stem or screw, substantially as described.

5. The combination of a divided standard or support for adjustable desks and seats, having a movable upper section or division provided with guide-rails and a fixed lower section or division, a bolt and nut with the stem of the bolt passing through the fixed section or division of the standard or support, and through a longitudinal slot in the body of the movable section or division of the standard or support with the nut of the bolt entered between guide-rails of the movable section or division of the standard or support, a threaded stem or screw having thereon a traveling nut, legs or steps on the movable section or division of the standard or support in engagement with the traveling nut, a bevel-pinion on the end of

the threaded stem or screw, a bevel-gear mounted in the fixed section or division of the standard or support and in mesh with the bevel-pinion, and a cap or cover attached to the fixed section or division of the standard or support including the gear and the threaded stem or screw and having a table or shelf forming a step for the end of the threaded stem or screw, substantially as described.

699,940. STOCKING-SUPPORTER. RALPH H. YAMMERS, Bham., and THOMAS HALL, Brooklyn, N. Y. Filed Aug. 4, 1906. Serial No. 26,592. (No model.)

Claim.—1. In a stocking-supporter, a head to enclose the heel with means for attaching it to the dress or belt above and means for supporting the stocking below, substantially as shown and described.

2. In a stocking-supporter, a clasp composed of a member B provided with a hinged ring at its lower end, an opening C and a portion E overhanging at its upper end, in combination with a member T having at its upper end a provision for support by cord or web, and its lower end shaped to pass into the hinged ring at lower end of member B substantially as shown and described.

3. In a stocking-supporter, a clasp composed of a member B provided with a hinged ring at its lower end, an opening C at its upper end, in combination with a member T having at its upper end a provision for support by cord or web and its lower end shaped to pass into the hinged ring at the lower end of member B and force into the ring a portion of the fabric to be supported, substantially as shown.

699,941. CONVERTIBLE TOOL. CHARLES S. ARNOLD, Greenwich, Mass. Filed Feb. 12, 1908. Serial No. 69,597. (No model.)

Claim.—1. A convertible tool having pivotally-connected members consisting of a head and a shank adapted to occupy a plurality of relative positions, one of said members being provided with an eye having a contour curved concentrically with the pivot and the other member having a shoulder overlapping and bearing upon the periphery of the eye of the other member, and means for securing the members in their adjusted relative positions.

2. A convertible tool having pivotally-connected members consisting of a head and a shank adapted to occupy a plurality of relative positions, said members having conical concave eyes peripherally concentric with the pivotal point of connection, and one of the members having a shoulder overlapping and bearing upon the periphery of the eye of the other member, and means for securing the members in their adjusted relative positions.

3. A convertible tool having pivotally-connected members consisting of a head and a shank, one of which is provided with an eye having a contour curved concentrically with the pivot and provided with a plurality of teeth, and a locking device consisting of a rotary button or bolt mounted in the other member for engagement with either of the said teeth and being notched or cut away at one side to give clearance and permit relative movement of the members.

4. A convertible tool having pivotally-connected members consisting of a head and a shank, said head having a pin, and means for securing the shank in adjusted positions with relation to the head, the shank in one of its positions being in engagement with said pin.

5. A convertible tool having pivotally-connected members consisting of a head and a shank, and means for securing said members in different relative positions, the head being provided with a pin for engagement with the shank in one of its positions.

6. A convertible tool having pivotally-connected members consisting of a head and a shank, and means for securing the same in different relative positions, the shank being provided with a handle-socket, and a handle-socket device consisting of a rotary button or bolt mounted in the wall of the socket for engagement with the notch in the handle and provided with a cut-away portion for registration with the socket to release the handle.

699,942. STARCHING-MACHINE. SAMUEL S. HANCOCK, Chicago, Ill. Filed Mar. 24, 1908. Serial No. 14,972. (No model.)

Claim.—1. In a starching-machine, in combination, a supporting-frame; a starch- receptacle; a starching-roller comprising a series of starching-rollers; a starching-wheel adapted to rotate in said starching-roller; said wheel carrying a series of starching-rollers; an endless open adapted to travel with the starching-rollers in said roller; an endless open adapted to travel with the starching-rollers on said starching-wheel to move said open at the same rate of speed with relation to each other; and means for rotating said wheel.

2. In a starching-machine, in combination, a supporting-frame; a starch- receptacle; two starching-rollers each comprising a series of starching-rollers; a starching-wheel for each of said starching-rollers, one of said wheels carrying a series of starching-rollers, the other wheel being provided with a series of rubbing-blocks; an endless open adapted to travel with the starching-rollers; an endless open adapted to travel with the starching-rollers; and means for rotating said wheel.

3. In a starching-machine, in combination, a supporting-frame; a starch- receptacle; three starching-rollers, each comprising a series of starching-rollers; a starching-wheel for each of said starching-rollers, two

of said wheels carrying a series of starching-rollers, the other one of said wheels being provided with a series of rubbing-blocks; an endless open adapted to travel with the starching-rollers in said roller; an endless open adapted to travel with the starching-rollers; and means for rotating said wheel.

4. In a starching-machine, in combination, a supporting-frame; a starch- receptacle; a substantially conical starching-roller pivotally supported within said receptacle; a starching-wheel rotatably mounted concentrically with the axis of the roller described by said roller; a peripheral series of starching-rollers on said wheel; a series of starching-rollers rotatably mounted in yielding bearings in said roller and adapted to be held in contact with the starching-rollers on said wheel; an endless open adapted to travel with the starching-rollers in said roller; an endless open adapted to travel with the starching-rollers on said starching-wheel; and means for rotating said wheel to move said open at the same rate of speed with relation to each other.

5. In a starching-machine, in combination, a supporting-frame; a starch- receptacle; a framework pivotally mounted within said starch- receptacle, said framework comprising two starching-rollers; a series of starching-rollers yieldingly mounted within said framework, for each of said rollers; a rotatable starching-wheel concentric with the axis of the roller described by one of said rollers; a starching-wheel concentric with the axis of the roller described by the other of said rollers, said last-mentioned starching-wheel being provided with a series of peripheral rubbing-blocks; a yieldingly-mounted roller having an elastic face intermediate said starching-wheels; an endless open adapted to travel with the starching-rollers of said rollers; an endless open adapted to travel with the starching-rollers of said rollers; and means for rotating said wheel.

6. In a starching-machine, in combination, a supporting-frame; a starch- receptacle; a framework pivotally mounted within said starch- receptacle, said framework comprising three starching-rollers, each provided with a series of starching-rollers rotatably mounted in yielding bearings, the rollers of each roller being disposed on the axis of a roller; three starching-wheels rotatably mounted in bearings in the supporting-frame, each of which starching-wheel is concentric with the axis of the roller described by said starching-roller, two of said wheels also being provided with a peripheral series of starching-rollers, the intermediate wheel having a peripheral series of rubbing-blocks; three rotatable rollers yieldingly supported in said frame and being provided with elastic faces; an endless open adapted to travel with the starching-rollers of said rollers; an endless open adapted to travel with the starching-rollers of said rollers; and means for rotating said wheel.

7. In a starching-machine, in combination, a supporting-frame; a starch- receptacle; a substantially conical starching-roller pivotally mounted within said starch- receptacle; said roller comprising a series of starching-rollers; a starching-wheel adapted to rotate in said starching-roller, said wheel carrying a peripheral series of rubbing-blocks; an endless open adapted to travel with the starching-rollers in said roller; an endless open adapted to travel with the starching-rollers on said starching-wheel; and means for rotating said wheel.

699,943. SHIRT-HANGER. CHARLES A. HANLEY, Philadelphia, Pa. Filed Mar. 22, 1901. Serial No. 62,282. (No model.)

Claim.—1. A shirt-hanger having a lower body portion consisting of a light open frame comprising four corner-uprights connected by cross-braces two of said corner-uprights extending all four uprights so as to leave an open space transversely through the mid body portion and the other two corner-uprights extending the upright in pairs and leaving a vertical space between the uprights and last-mentioned two corner-uprights, in combination with a journal-bolt arranged in the open space between all the corner-uprights and vertical and horizontal screws carried by said corner-uprights for holding the journal-bolt in position.

2. In a shirt-hanger the combination of four depending arms A of single-bow substantially equidistant at the bottom and spreading at the top to form a large supporting-base, transverse plates C pivoted to the upper ends of the said arms to properly space them in pairs, means B connecting the lower portions or extensions of the arms in pairs, upper and lower transverse plates D and E for connecting the two pairs of arms A at points above

and below the brace H, a removable journal-box J arranged between the brace H, F and E, and adjusting and supporting covers A, f and c for said box carried respectively by said brace.

3. In a shaft-hanger the combination of four depending arms A of angle-iron substantially equidistant at the bottom and spreading at the top to form a large supporting-base and in which the lower portions of the arms are made detachable from the upper portions, transverse plates O pivoted to the upper ends of the said arms to properly space them in pairs, braces H connecting the lower portions or extensions of the arms in pairs below the union of the upper and lower portions of the arms A, upper and lower braces F and E for connecting the lower portions of the two pairs of arms A at points above and below the brace H but also arranged below the union of the upper and lower portions of the said arms A, a removable journal-box J arranged between the brace H, F and E, and adjusting and supporting covers A, f and c for said box carried respectively by said brace.

4. A shaft-hanger having a lower body portion consisting of four upright angle-irons, combined with braces for connecting said uprights in two pairs, two other braces for connecting the two pairs of uprights into a single structure said last-mentioned braces being arranged respectively above and below the level of the first-mentioned braces, and a journal-box supported between the four braces and four uprights.

5. A drop-hanger consisting of a body portion comprising four upright flanged metal members flaring or spreading at the top, combined with transverse plates connecting the tops of the members to form an extended base, braces H H rigidly connecting the said members in pairs, braces F and E connecting the pairs of members together and located respectively at a higher and lower elevation than the brace H, a journal-box J arranged between the braces, and covers passing through the braces and supporting the journal-box.

6. A shaft-hanger frame formed of flanged metal bars and having its body portion formed of four upright members united at the top by transverse plates O O and the two curved angle-iron bars B B secured together at their middle portions and having their ends secured to the upright members.

7. In a drop-hanger the combination of four upright members, transverse side braces connecting said upright members in two pairs, a transverse brace connecting the two pairs of upright members at a level above the side braces, and a second transverse brace between the two pairs of upright members and at a level below the side braces, detachable means for connecting the last-mentioned and lowermost brace to the upright members, supporting and adjusting covers carried by the braces, and a journal-box supported by said covers.

699,944. FORMALDEHYDE-GAS GENERATOR. EDWARD W. GARDNER and FREDERICK H. LAWRENCE, Fleming, N. Y. Filed Feb. 4, 1908. Serial No. 88,548. (No model.)

Claim.—1. As a new article of manufacture, the formaldehyde-gas generator comprising the tablet 12 of para-formaldehyde and the tablet 13 of carbon thoron and at its base substantially of the same surface area as the upper surface of said tablet 12; substantially as and for the purposes set forth.

2. As a new article of manufacture, the formaldehyde-gas generator comprising the tablet 12 of para-formaldehyde and the tablet 13 of carbon thoron and at its base substantially of the same surface area as the upper surface of said tablet 12, combined with a non-inflammable covering extending up the sides of said tablet 12 to said tablet 13; substantially as and for the purposes set forth.

3. As a new article of manufacture, the formaldehyde-gas generator comprising the tablet 12 of para-formaldehyde and the tablet 13 of carbon thoron and at its base substantially of the same surface area as the upper surface of said tablet 12, said tablet 13 above its base being substantially of cone shape; substantially as and for the purposes set forth.

699,945. BURIAL-CASE PROTECTOR. JOHN B. CLARK, Columbus, Ohio. Filed Oct. 10, 1907. Serial No. 78,188. (No model.)

Claim.—1. In a burial-case protector, the combination with a bottom frame comprising a central bar formed of hinged sections and laterally-extended end-bars, said bars being when horizontal of greater length than

the length and width of the grave in which they are intended for use, of a coffin-containing case mounted on said bottom frame, an external jacket including the sides, ends and top of said coffin-containing case, vertical standards rising from said bottom frame on the upper sides of said jacket, each extending across the upper side of the jacket and locked in connection with said standards, substantially as specified.

2. In a burial-case protector, the combination with a bottom frame comprising united bars adapted to have their ends projecting into the walls of a grave, and a coffin-containing case supported on said bottom frame-bar, of hollow locking-standards rising from said bottom frame-bar, each of said standards having on its inner side a projecting tooth 17, a spring 18 opposite the same and the upper portions of said standards having transverse keyways or openings 19, longitudinal and transverse frame-bars 18 and 19 extending over the burial-case and having openings in their outer end portions adapted to receive the upper portions of said standards 12, a block 20 detachably mounted on each of said standards above the corresponding top frame-bar and having a projecting bar engaging the opening of said frame-bar, a block 20 fitting over the upper end of each of said standards and bearing upon the block 20, a key-block 26 having a central opening therein and adapted to be inserted in one of the openings 19 and a locking-bar adapted to be inserted vertically through said block 26 and into the standard 12, said bar having formed in its lower portion teeth 28 having an enlarged head as described adapted to enter the opening of the block 26, substantially as specified.

699,946. PRINTING-MACHINE. THOMAS CONRAD, Geneva, Switzerland. Filed Oct. 20, 1906. Serial No. 754,165. (No model.)

Claim.—1. In an offsetting-cylinder printing-machine, means for automatically and intermittently feeding the paper to be printed from the web, consisting of a sliding frame, a rack on said frame geared to a driven toothed wheel, spring-clippers for engaging the paper, and a novel independently-movable frame carried by the first-mentioned frame, substantially as shown and described.

2. In an offsetting-cylinder printing-machine for printing from the web, the combination with a sliding frame, of a curved frame carried by said sliding frame, gear-wheels centered on the sliding frame engaging racks on the curved frame, a quadrant-arm for actuating said gear-wheels

and a rack which controls the movement of said quadrant-arm, substantially as shown and described.

3. In an offsetting-cylinder printing-machine for printing from the web, the combination with a quadrant-arm, of a rack for controlling the movement of said quadrant-arm, said rack being jointed and adjustable by the action of curved spindles upon nuts on the rack, to lengthen or shorten the path of the quadrant-arm controlled by the rack, substantially as shown and described.

4. In an offsetting-cylinder printing-machine for printing from the web, the combination with a quadrant-arm, of means for changing the direction of movement of the quadrant-arm and ultimate direction of the feed consisting of levers connected to the pivoted portions of the rack, rods connecting them together, a rod connecting one of the pivoted portions to a dotted quadrant and a second rod connected to said quadrant and carrying a roller operated by a cam, substantially as shown and described.

699,947. OPERATING-HALTER. ROBERT W. BLAIR, New York, N. Y. Filed Mar. 6, 1908. Serial No. 81,871. (No model.)

Claim.—1. As a new manufacture, an operating-halter composed of side straps, a bridge connected with said straps for engaging the animal's nose, a yoke connected with the side straps for insertion beneath the animal's upper lip, and side guys connected to said yoke, substantially as set forth.

2. As a new manufacture, an operating-halter composed of side straps, a bridge connected with said straps for engaging the animal's nose, a yoke connected with the side straps for insertion beneath the animal's upper lip, side guys connected to said yoke, and means for adjusting said yoke, substantially as set forth.

3. As a new manufacture, an operating-halter composed of side straps, a bridge connected with said straps for engaging the animal's nose, a carriage connection to said bridge, a yoke connected with the side straps for insertion beneath the animal's upper lip, and side guys connected to said yoke, substantially as set forth.

4. As a new manufacture, an operating-halter composed of side straps, a bridge connected with said straps for engaging the animal's nose, a loop connected with the side straps for insertion beneath the animal's upper lip, side guys connected to said loop, a yoke connected to said bridge, and a carriage connection to said yoke, substantially as set forth.

5. As a new manufacture, an operating-halter composed of side straps, a bridge connected with said straps for engaging the animal's nose, a loop connected with the side straps for insertion beneath the animal's upper lip, side guys connected to said loop, a yoke movably connected to said bridge, and a carriage connection to said yoke, substantially as set forth.

6. As a new manufacture, an operating-halter composed of side straps, a bridge connected with said straps for engaging the animal's nose, a loop connected with the side straps for insertion beneath the animal's upper lip, side guys connected to said loop, and a tubular protecting-paddling on said loop, substantially as set forth.

7. As a new manufacture, an operating-halter composed of side straps, a bridge connected with said straps for engaging the animal's nose, a loop connected with the side straps for insertion beneath the animal's upper lip, side guys connected to said loop, and a rubber tube on said loop for protecting the same, substantially as set forth.

8. As a new article of manufacture, an operating-halter comprising side straps, a rigid bridge connected to said straps and engaging the animal's nose, said bridge having offset portions coincident with the cheeks, and side guys connected to said halter, substantially as set forth.

9. As a new article of manufacture, an operating-halter comprising side straps, a bridge connected to said straps and engaging the animal's nose, said bridge having offset portions coincident with the cheeks, a padding for said bridge, and side guys connected to said halter, substantially as set forth.

699,948. YARN-PRINTING MACHINE. JAMES HAMILTON, Philadelphia, Pa., assignor to James Dunlop Carpet Company, Philadelphia, Pa., a Corporation of Pennsylvania. Filed Apr. 18, 1908. Serial No. 81,348. (No model.)

Claim.—1. In a yarn-printing machine, the combination with the yarn-draw, the carriage, the color-bar and its wheel, and the rubbing device on the respective ends of the carriage, of a horizontally-disposed bar, upwardly-inclined ends supporting said bar, rock-shafts carrying said ends, other ends extending downwardly from said rock-shafts, and links coupling said last-mentioned ends to cause them to operate as a unit; device operating to maintain the horizontal bar normally elevated, and means to effect an opposite lowering movement of said bar when desired.

2. The combination with the yarn-draw, the carriage, the color-bar and its wheel, of the rubbing device at the respective ends of the carriage, said device comprising each a vertically-movable support, a spring-controlled link pivotedly mounted in an independent bearing at the upper end of said support, operating to maintain the same yieldingly in position, springs to maintain said supports in normal position, a roller, a dotted bearing member pivotedly mounted on the lower end of said support, a horizontally-arranged lifting-bar having an inclined end, with actuating means operated by a treadle to bring said bar into the path of said roller; substantially as described.

3. The combination with the yarn-draw, the carriage, the color-bar and its wheel, of the rubbing device at the respective ends of the carriage, said device comprising each a vertically-movable post, means to maintain it in normal position, a stem independently movable on said post, a spring to maintain said stem normally raised, a spring-controlled link pivotedly mounted on said stem, together with means for bodily raising the said post with its connections, substantially as described.

4. The combination with a yarn-drive, the carriage, the color-bar, the color-wheel, the rubbing device on the opposite ends of said carriage, means to yieldingly support each rubbing device in an independently-movable path, spring devices to maintain the said parts in normal position, and means to raise said parts against counter spring action; substantially as described.

699,949. CHORDOLA CAR. HARRY S. HARR, Chicago, Ill., assignor to Hodge Patent Car Company, Chicago, Ill., a Corporation of Illinois. Filed Aug. 10, 1901. Serial No. 71,545. (No model.)

Claim.—1. In a car of the class described, the combination of a frame portion provided with swinging doors forming side boards thereof, a rock-shaft arranged to directly and positively contact the free end of each swinging door between the bearing portions of each rock-shaft and held in its locked position, an integral crank-arm upon the shaft, each pivoted at its outer end at a point concentric from the rock-shaft to permit the shaft to swing to and from the door, substantially as described.

2. In a car of the class described, the combination of a frame portion provided with swinging doors forming side boards thereof, a swinging rock-shaft provided with crank-arms upon which it is swingingly mounted each crank-arm being arranged in reliable bearings in the frame portion at or near each side thereof and each shaft being adapted to be swung into and held in direct positive contact with the free ends of the swinging doors between the bearing portions of each shaft and adapted to force each door into and hold them locked in their closed position, substantially as described.

3. In a car of the class described, the combination of a frame provided with swinging doors forming side boards thereof, a swinging rock-shaft, integral crank-arms on the shaft pivoted at their outer ends at points concentric from the main portion of the rock-shaft and at substantially right angles with the outer surface of the door when closed, and the point of the rock-shaft's contact with the door, substantially as described.

4. In a car of the class described, the combination of a frame portion, swinging doors forming side boards thereof, a swinging rock-shaft arranged at each side of the car, a plurality of integral crank-arm portions upon each rock-shaft having their outer ends pivotedly mounted at points concentric from the main portion of the shaft and at substantially right angles with the outer surface of the door when closed, and the point of contact with the door, and means for swinging the shaft into and out of positive contact with the lower ends of the swinging doors, substantially as described.

5. In a car of the class described, the combination of a frame portion, swinging doors forming side boards thereof, a swinging rock-shaft mounted at each side of the car adjacent to the lower ends of the doors, a plurality of integral crank-arm portions upon each shaft pivotedly mounted in the frame at points substantially at right angles with the outer surface of the doors when closed, and the point of contact with each door,

each crank-arm being of such length as to reach only to the edge of the door nearest the pivotal point of the rock-shaft, and means for swinging the rock-shaft into and out of positive contact with the lower ends of each door, substantially as described.

6. In a car of the class described, the combination of a frame portion, swinging doors forming side boards thereof, a rock-shaft for each side of the car arranged at the lower ends of each door having a plurality of ball portions each adapted to extend lengthwise of one of the doors from end to end thereof, a pair of integral crank-arms for each ball portion connected thereby and having their outer ends pivotedly mounted concentric with the ball portions and at substantially right angles with the outer surface of the doors when closed, and the point of contact with the door, and means for swinging the rock-shaft into and out of positive contact with each door, substantially as described.

699,950. ELECTRICALLY-DRIVEN ROLLING-MILL. HENRY HARVEY, Philadelphia, Pa., assignor to Morse, Williams and Company, a Corporation of Pennsylvania. Filed Jan. 10, 1901. Serial No. 64,701. (No model.)

Claim.—1. The combination of the two rolls of a rolling-mill, with two vertical shafts and connecting worm and worm-wheel gearing arranged upon opposite ends of the two rolls for independently and mechanically rotating the respective rolls, a transverse power-shaft carried in reliable bearings on the top of the housings of the rolling-mill, and independent connecting-gearing between the ends of the power-shaft and the upper ends of the two vertical shafts.

2. The combination of the two rolls of a rolling-mill, with two vertical shafts and connecting worm and worm-wheel gearing arranged upon opposite ends of the two rolls for independently and mechanically rotating the respective rolls, a horizontal transverse and diagonally-arranged power-shaft carried in reliable bearings on the top of the housings of the rolling-mill, and independent connecting-gearing between the ends of the power-shaft and the upper ends of the two vertical shafts.

3. In a rolling-mill, the combination of the housings and horizontal rolls journaled therein one of which has its end projecting beyond the end of the other roll, a motor for operating the roll mounted on top of the housings and above the rolls and provided with a transverse power-shaft, a worm-wheel carried to the projecting end of the roll and extending beyond the line of the shorter end of the other roll, an upright shaft extending from the level of the rolls to the power-shaft, gearing between the power-shaft and upright shaft, and a worm on the upright shaft gearing with the worm-wheel of the rolls.

4. In a rolling-mill, the combination of the housings and horizontal rolls journaled therein one of which has its end projecting beyond the end of the other roll, a motor for operating the rolls mounted on top of the housings and above the rolls and provided with a transverse power-

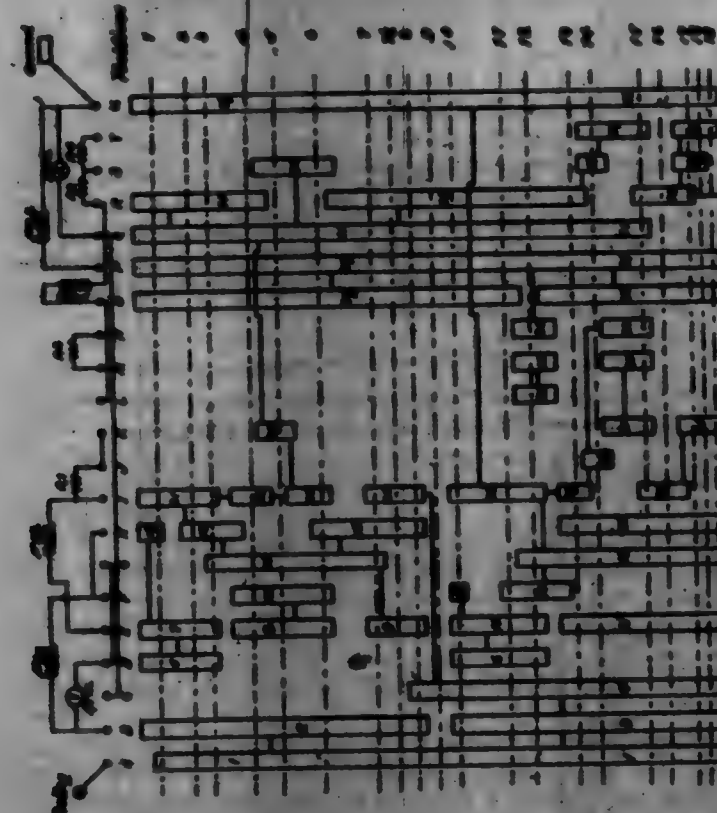

shaft, a worm-wheel secured to the projecting end of the roll and extending beyond the line of the shorter end of the other roll, an upright shaft extending from the level of the rolls to the power-shaft, gearing between the power-shaft and upright shaft, a worm on the upright shaft gearing with the worm-wheel of the rolls, and a casing inclosing the worm and worm-wheel gearing secured to the housing and provided with a bearing for the upright shaft.

5. In a rolling-mill, the combination of the housings and the two rolls, with a motor for rotating the rolls arranged immediately above and supported by the housing, and two sets of power-transmitting connections between the motor and the opposite ends of the respective rolls for rotating them in opposite directions.

6. In a rolling-mill, the combination of the housings, the two rolls having their operating-shafts extended through the housings in opposite directions, worm-wheels secured upon said extended roll-shafts, worms meshing with opposite sides of said respective worm-wheels upright shafts for operating the worms, and a diagonally-arranged power-shaft carried in bearings upon the upper part of the housings and having its ends mechanically connected with the upper ends of the upright shafts.

7. In a rolling-mill, the combination of the housings the two rolls having their operating-shafts extended through the housings in opposite directions, worm-wheels secured upon said extended roll-shafts, worms meshing with opposite sides of said respective worm-wheels upright shafts for operating the worms, a diagonally-arranged power-shaft carried in bearings upon the upper part of the housings and having its ends mechanically connected with the upper ends of the upright shafts inclosing casings surrounding the worms and worm-wheels secured to the housings at different elevations and provided with bearings for the upright shafts.

699,951. ELECTRIC CONTROLLER. JOHN C. HENRY, Denver, Colo.; RALPH A. HENRY, assignor of said John C. Henry, deceased, assignor to Stanley Electric Manufacturing Company, a Corporation of New Jersey. Filed Apr. 1, 1901. Serial No. 54,000. (No model.)

Claim.—1. The method of regulating an electric motor which consists in connecting the field-coils so that on starting the motor may be connected as a compound machine, having one portion of its high-resistance field in series with its armature and the other portion in shunt therewith, changing said shunt-portion to long shunt, so that it embraces the series portion and then connecting both of said field-coils in shunt with the armature.

2. The method of regulating an electric motor, which consists in connecting the field-coils so that on starting the motor may be connected as a compound machine, having one portion of its high-resistance field in series with its armature and the other portion in shunt therewith, changing said shunt-portion to long shunt so that it embraces the series portion, and then connecting both of said field-coils in shunt and further regulating by varying the current in said field.

3. The method of regulating a pair of electric motors which consists in starting one of them as a compound machine, using a portion of the ordinary shunt-coil as a series coil, changing the shunt connection to long

shunt and then to regulate shunt combination cutting one of the said motors from the circuit by first reversing a part of its field-coils, and then connecting it in parallel in the same manner as it was previously started.

4. The method of changing motors from series to parallel, consisting in reversing a part of the field-coils of one of the motors so as to neutralize its magnetism, opening the armature-circuit, allowing the current to pass through the field in series with the other motor, then short-circuiting and removing the field of the first-named motor from the circuit and connecting the motors in parallel.

5. The method of operating a pair of electric motors, which consists in connecting the armatures in series relation, and the field in shunt relation thereto, changing the combined machines to parallel, and then speeding-up by increasing the resistance of the field-circuit by changing the field-coils from parallel to series relation, and by inserting resistances.

6. The method of operating a pair of electric motors, which consists in connecting the armatures in series relation and the field in shunt relation thereto, changing the combined machines to parallel and then speeding-up by placing the field of both motors in series.

7. The method of operating a pair of electric motors which consists in connecting the armatures in series relation and the field-coils partly in series and partly in shunt relation, and then changing the field-coils wholly to series relation.

8. The method of operating electric motors which consists in reversely connecting a part of the coils of a motor to neutralize the field thereof, and then opening the armature-circuit.

699,952. CIRCUIT-CONTROLLER. RICHARD BERNARD, London, Eng. Filed Oct. 7, 1901. Serial No. 71,702. (No model.)

Claim.—1. In a circuit-controller, the combination with a supporting-frame, a plate supported by said frame, studs mounted in said plate, contact-fingers arranged in pairs on said studs, and contact-blades movable in the arc of a circle to make and break contact with said fingers.

2. In a circuit-controller, a supporting-plate, studs mounted in said plate, collars mounted on said studs, a pair of contact-fingers carried by each collar, and contact-blades movable in the arc of a circle between the pairs of fingers to make and break contact therewith.

3. In a circuit-controller, a segmental supporting-plate, studs mounted in said plate, collars mounted on each of said studs, a pair of contact-fingers mounted in recesses provided therein in each collar, and contact-blades movable in the arc of a circle between the fingers to make and break contact therewith, substantially as described.

4. In a circuit-controller, a supporting-plate, one or more studs mounted in said plate, collars mounted on the stud or studs with their opposite faces recessed, contact-fingers mounted in said recesses, and contact-blades movable between the fingers to make and break contact therewith.

5. In a circuit-controller, a series of suitably-supported studs, collars mounted on each of said studs, with their opposite faces recessed, and contact-fingers mounted in said recesses for engagement with opposite faces of contact-blades to make and break contact.

6. In a circuit-controller, a series of suitably-supported studs, collars mounted on said studs, a pair of contact-fingers carried by each of said collars, one pair of said fingers being insulated from the supporting-plate, and contact-blades movable between the fingers, substantially as described.

7. In a circuit-controller, a series of suitably-supported studs, collars mounted on said studs, a pair of contact-fingers carried by each of said collars, one pair of the fingers having an oscillating movement, and contact-blades movable in the arc of a circle between the fingers.

8. A multiple-circuit-controller, comprising a series of electrically-connected spring-fingers arranged in pairs, one pair of fingers being ex-

ble of oscillatory movement on their support, and segmental contact-blades movable in the arc of a circle between the pairs of fingers for contact therewith.

9. A multiple-circuit controller comprising a series of suitably-mounted spring contact-fingers one of which is capable of oscillatory movement on its support, and contact-blades movable between the fingers in the arc of a circle for engagement with the fingers.

10. In a multiple-circuit controller, a supporting-plate, slant mounted in said plate and insulated therefrom, collars mounted on each of said studs, a pair of spring contact-fingers carried by each of said collars, one of said collars and fingers twisted thereby being insulated from their stud, and contact-blades movable in the arc of a circle between the fingers and provided with knife-edges, as and for the purpose described.

11. A multiple-circuit controller embodying a support, slant mounted therein and insulated therefrom, collars mounted on said studs, a pair of spring-fingers carried by each of said collars, one of said pairs of fingers capable of oscillatory movement, and contact-blades which are movable between the pairs of fingers to make and break contact therewith.

12. In a circuit-controller, a support, a stud mounted in said support, a collar mounted on said stud to partially rotate thereon, a pair of spring-fingers carried by the collar and movable therewith, means for limiting the movement of said collar and fingers, and a contact-blade movable between the fingers to make and break contact therewith.

13. In a circuit-controller, a support, a stud mounted thereon, collars mounted on said stud, a pair of spring-fingers carried by each of said collars, and contact-blades movable in the arc of a circle between the fingers to make and break contact therewith.

699,958. **IMP AND WRINGER THEREFOR.** HOWARD BRUSH, Chicago, Ill. Filed Aug. 20, 1901. Serial No. 73,399. (No model.)

Claim.—1. The combination of a bifurcated body, with a handle pivotedly secured thereto, a ball secured on the body and extending crosswise one of its ends, a sleeve movably located on the handle and having means to fix it thereto, a rod or shaft journaled on said sleeve, a map secured at one of its ends to said rod or shaft and at its other end to the said ball, and means to rotate the shaft, substantially as described.

2. The combination with a bifurcated body, of a handle pivotedly connected thereto between its prongs, a ball secured on the body and extending crosswise one end thereof, a rib secured longitudinally on said handle, a sleeve movably secured on the handle and having means to fix it thereto, a shaft journaled on said sleeve, a map secured at one of its ends to said shaft and at its other end to the ball, and means to rotate the shaft, substantially as described.

3. The combination of a bifurcated body, with a handle pivotedly connected thereto between its prongs, a map connected to one end of said body, and means movably secured on the handle and connected to the other end of the map to raise, lower and twist the same, substantially as described.

4. The combination with a bifurcated body, of a handle pivotedly connected thereto between its prongs, a sleeve secured longitudinally on the handle, a shaft journaled on said sleeve, a beveled gear on said shaft, a map connected at one of its ends to said shaft and at its other end to the ball, a crank-shaft journaled on the sleeve at right angles to the first-named shaft, and a beveled gear on the crank-shaft, substantially as described.

699,959. **MANUFACTURE OF OPEN WEAVED FABRIC.** BENJ. A. HENNER, Allentown, Pa. Filed May 4, 1905. Serial No. 84,895. (No model.)

Claim.—1. The process of knitting open stripes, which consists in causing single needles, corresponding in position to the stripes to be produced, to receive and draw down thread with the rest of the needles, and thereafter to cast off this thread, prior to again receiving the thread for the next course of knitting, substantially as described.

2. The process of knitting hosiery with open stripes down the back, which consists in causing single needles, corresponding in position to each such stripe to be produced, to successively retreat and cast off the thread of the preceding course, and then to receive the thread of the succeeding course, and then to again retreat with the rest of the needles and pull out an amount of thread by which each space free from knitting which these needles occasion is broader than would be produced by the mere omission of a single needle, substantially as described.

3. The process of knitting hosiery with open stripes down the back, which consists in causing single needles, corresponding in position to each such stripe to be produced, to successively retreat and cast off the thread of the preceding course, and then to receive the thread of the succeeding course, and then to again retreat and pull thread with the rest of the needles, and so on, until the leg of the stocking is knit, and thereafter knitting the heel and sole with the single needles operating as do the rest of the needles, substantially as described.

699,955. **MEASURING APPARATUS.** FRANK BRY, St. Louis, Mo. Filed Sept. 20, 1901. Serial No. 77,979. (No model.)

Claim.—1. In a measuring apparatus, a suitable tank; a measuring-receptacle mounted below the tank; a connection between the tank and the measuring-receptacle so that liquid will run from the tank into the receptacle; a valve controlling the said connection; a piston mounted in said receptacle; a piston-rod extending from said piston through the head of said receptacle; cross-arms mounted on the rear end of said piston-rod outside of the receptacle; connecting-rods extending from the ends of said

cross-arms forwardly; a shaft mounted above the forward end of said receptacle; cross-arms extending from the ends of said shaft and connected to the forward ends of said connecting-rods; an indicator-plate extending upwardly from the forward end of said receptacle in front of the storage-tank; a wheel mounted in front of said indicator-plate; a crank-pin carried by said wheel; a crank-arm extending from the center of said shaft; and a connecting-rod connecting said crank-pin to said cross-arm, as required to reciprocate the piston by the rotation of the wheel, or as required to rotate the wheel when liquid is admitted to the measuring-receptacle and operates the piston, substantially as specified.

2. In a measuring apparatus, a suitable tank; a measuring-receptacle mounted below the tank; a connection between the tank and the measuring-receptacle, so that liquid will run from the tank into the receptacle; a piston in said measuring-receptacle; a piston-rod extending from the piston through the head of the receptacle; cross-arms mounted upon the outer end of the piston-rod; connecting-rods extending forwardly from the ends of the cross-arms; a shaft mounted above the measuring-receptacle in front of the storage-tank; cross-arms extending from the ends of said shaft and connected to the forward ends of said connecting-rods; an indicator mounted in front of the storage-tank; an indicator-wheel mounted in front of the indicator, and having a finger pointing to the indicator; a crank-pin carried by the wheel; a crank-arm extending forwardly from the shaft; and a connecting-rod connecting the crank-pin to the cross-arm, as required to move the indicator when liquid is admitted to the measuring-receptacle to operate the piston, substantially as specified.

699,956. **GARMENT-HANGER.** JOHN JENNISON, New York, N.Y. Filed Aug. 19, 1901. Serial No. 73,990. (No model.)

Claim.—1. A garment-hanger comprising a segmental support, secured to a suitable containing device, a rod or arm pivotedly connected with said containing device at the center of a circle of which the segmental support forms a portion, said rod or arm being adapted to swing in a horizontal plane and the free end of said rod or arm being adapted to rest upon and move upon said segmental support, substantially as shown and described.

2. A closet, cupboard, wardrobe or other similar article provided with a top shelf, a garment-hanger connected with the bottom of said shelf and comprising a segmental support, and a rod or arm pivoted to the shelf at the center of a circle of which said segmental support forms a portion, the free end of the rod or arm being adapted to rest upon and move upon said segmental support, substantially as shown and described.

3. A garment-hanger comprising a segmental support secured to a suitable containing device and provided with a segmental groove in the top thereof, a rod or arm pivotedly connected to said containing device at the center of a circle, of which the segmental support forms a portion, said rod or arm being adapted to swing in a horizontal plane and the free end thereof being provided with an antifriction-roller which runs in the segmental groove of the segmental support, substantially as shown and described.

699,957. **MACHINE FOR CLEANING BLACKBOARD-WRASHERS.** JAMES A. JOHN, Leavenworth, Ind. Filed Jan. 14, 1905. Serial No. 80,795. (No model.)

Claim.—1. An eraser-cleaner having a movable member, an eraser-holder secured to said member, and means for automatically engaging and disengaging an eraser.

2. An eraser-cleaner having a movable member, an eraser-holder secured to said member, springs for moving an eraser thereto, and an automatically engaging and disengaging mechanism.

3. An eraser-cleaner having a movable member, an eraser-holder secured to said member and provided with a convex face, springs on the sides thereof, and a tripping device connected to said springs.

4. An eraser-cleaner having a movable member provided with a block having eraser-engaging springs thereon, a vertically-movable tripping-rod, and connections between the springs and said rod.

5. An eraser-cleaner having a movable member, an eraser-holder secured to said member, and means for feeding erasers to the eraser-holder.

6. An eraser-cleaner having a movable member, an eraser-holder secured to said member and a revolvable feed device engaging the side of an eraser to feed the eraser to the holder.

7. An eraser-cleaner having a movable member, an eraser-holder secured to said member, and rolls engaging one side and one face of an eraser.

8. An eraser-cleaner having a movable member, an eraser-holder secured to said member, a perforated plate on which erasers are broken, and means for feeding erasers to the holder.

9. An eraser-cleaner having a movable member, an eraser-holder secured to said member, and a brush for engaging the face of an eraser after it has been broken.

10. An eraser-cleaner having a movable member, an eraser-holder secured to said member, an eraser-feed mechanism, a perforated plate on which the erasers are broken, an opening in said plate beyond the perforations, and a brush engaging the face of an eraser while passing over said opening.

11. An eraser-cleaner having a movable member, an eraser-holder secured to said member and provided with springs to engage an eraser, means engaging the springs, rolls for feeding erasers to the eraser-holder, one of which rolls is provided with a groove, and an elongated flat-like trip engaging the grooved roll.

12. An eraser-cleaner having a movable member provided with an eraser-holder having springs to engage an eraser, a roll and a resilient rod engaging the sides of an eraser, rolls engaging the face of the eraser, and an automatic tripping device for releasing an eraser from the holder.

13. An eraser-cleaner having an indexing casing, inlet and discharge eraser openings provided with closures, means for breaking erasers, a chute for conducting erasers, and means for feeding erasers to the holders of the breaking mechanism.

14. An eraser-cleaner having a plurality of movable members provided with eraser-holders, means for feeding erasers to each holder, a shaft having cranks connected to said movable members, and an operating mechanism engaging said shaft.

15. An eraser-cleaner having a movable member provided with an eraser-holder, a table or plate on which erasers are broken having an opening therein, feed-rolls under the plate and in said opening, a chute above the opening, a discharge for erasers, and means for imparting motion to the movable member.

699,958. **GASTER.** JOHN F. KELLY, St. Louis, Mo. Filed Nov. 5, 1901. Serial No. 81,990. (No model.)

Claim.—An adjustable center comprising a tubular casing having the laterally-curved-throated lower portion 1; and a smaller upper portion 2; the nipple 3 adjustably secured to said larger portion 1; the center having the bracket 4 to engage the lower end of the nipple 3; and the vertical rod 5 extending through the nipple 3 into the smaller upper portion 2 of the casing, said upper-portion 2 serving as a bearing to support the upper end of the rod 5, substantially as specified.

699,959. CELLAR OR CISTERN DRAINER. WILLIAM B. LARSEN, South Bend, Ind., assignor of one-half to Joseph G. Bush, Milwaukee, Wis. Filed Jan. 7, 1901. Serial No. 61,494. (No model.)

Claim.—In a drainer, the combination of a vertical steam-inlet pipe having two right-angled bends to dispose its discharge and vertically upward and an automatic float-valve to control the supply of steam, a stand having horizontal laterally-offset legs and converging arms which terminate in a supporting-base to which the discharge end of the inlet-pipe is secured, a vertical ejecting-chamber having a series of perforations near its bottom supported on said base, ejecting-tubes in the chamber and a vertical discharge-pipe connected to the top of the chamber in alignment with the discharge end of the inlet-pipe and the tubes, the whole adapted to be supported on the stand whereby the drainer is portable.

699,960. PLEASURE-RAILWAY. ERIC LARSEN, Coney Island, N. Y. Filed Oct. 17, 1901. Serial No. 70,002. (No model.)

Claim.—1. A pleasure-railway comprising suitable supports, an inclined track or way suspended thereby, said track or way consisting of two separate parallel parts substantially in the form of double T-rails and connected shafts or axles placed in said track or way and provided with wheels which rest in said rails and with laterally-directed antifriction wheels or rollers which bear on the central portions of said rails, said shafts or axles being also provided with depending supports and a derrick animal suspended thereby, substantially as shown and described.

2. A pleasure-railway comprising suitably-supported inclined tracks or ways consisting of parallel members, the adjacent sides of which are provided with horizontal flanges, and connected shafts or axles provided with wheels which rest on said flanges and with laterally-directed antifriction-rollers which bear on the body portion of said track members, said shafts or axles being also provided with depending supports substantially as shown and described.

699,961. TUG-STOP. OLIVER P. LANSBURY, St. Louis, Mo. Filed Dec. 9, 1901. Serial No. 59,570. (No model.)

Claim.—A shaft-tag stop comprising a metallic strap or ring, the ends of which are turned parallel to each other, and provided with slots; a bolt through said slots to form a clamp; lateral projections extending from opposite sides of the ring or strap; and a projection extending outwardly from the ring and serving as a stop for the tag, substantially as specified.

699,962. VEHICLE BRAKE. BLAUWERT H. LUTER, Waverly, N. Y., assignor of one-half to Elsworth Gamble, Waverly, N. Y. Filed Sept. 16, 1901. Serial No. 70,642. (No model.)

Claim.—1. A vehicle-brake comprising a friction-drum fixed to one of the vehicle-axles, a friction-band encircling the drum, a pair of bell-crank levers, the ends of the band being connected to the lower ends of the said levers, a rod secured to the outer face of the brake-band and having its upper end hooked to engage a bracket on the running-gear for supporting the said brake-band, a link pivoted between the upper ends of the said levers, a vertically-arranged rod pivoted at its lower end to the brake-band, a short link connecting the free ends of the said link and rod, and a brake-rod secured to said short link.

2. A vehicle-brake, comprising a friction-drum fixed to one of the vehicle-axles, a friction-band encircling the drum, a pair of bell-crank levers, the ends of the band being connected to the lower ends of the bell-crank levers and the upper ends of said bell-crank levers being secured to a brake-rod, a rod secured to the outer side of the brake-band and having its upper end hooked to engage a bracket on the running-gear for supporting the said brake-band, a link provided with a central screw-threaded opening for the reception of the brake-operating rod, and a pair of rods pivoted to the upper and lower sides of the said link for supporting the same, the upper rod being secured to the said bell-crank levers and the lower rod secured to the said brake-band-supporting rod.

3. A vehicle-brake, comprising a friction-drum fixed to one of the vehicle-axles, a friction-band encircling the drum, eye-pieces secured to the ends of said friction-band through the medium of which the band may be adjusted, a rod provided with a hooked end secured to the said friction-band for supporting the same, a sliding block arranged upon said bar, adjacent its hooked end for preventing displacement of the same, a pair of bell-crank levers pivoted to the eyes of the said friction-band, and extending on either side of the said supporting-rod, a brake-rod attached to said bell-crank levers and means for operating said brake-rod.

699,963. REVERSING DEVICE. EDWARD J. LUTER, Northampton, England. Filed Nov. 21, 1901. Serial No. 69,000. (No model.)

Claim.—In a machine of the class described, a frame, a rotatable shaft mounted therein and provided with several threads, a reciprocating member mounted on said shaft and provided with two sets through which the shaft passes, the said sets being divided horizontally into two separated parts or halves, one of said parts or halves being provided with a left-hand and the other with a right-hand thread and means for alternately raising and lowering the upper halves of said sets as the reciprocating member is operated, said reciprocating member being adapted to be operated by the turning of said shaft, substantially as shown and described.

699,964. ELECTROLYTIC CONVERTER. FRANKLIN E. LEE, Chicago, Ill., assignor to Ross J. Denny, trustee, Muncie, Ind. Filed Oct. 15, 1906. Serial No. 35,692. (No model.)

Claim.—1. In electrolytic converter, the combination with the closed redox vessel having the anode and cathode terminals and the interposed diaphragm dividing the vessel into upper anode and lower cathode chambers, of a combined separator and vent-pipe connected to the cathode-chamber beneath the diaphragm extending upwardly above the level of said diaphragm and having a free outlet for the gases, substantially as described.

2. In electrolytic converter, the combination with the closed redox vessel having the anode and cathode terminals and an interposed, substantially horizontal diaphragm dividing the vessel into upper anode and lower cathode chambers, of a combined separator and vent-pipe connected to the cathode-chamber beneath the diaphragm and extending upwardly beyond the diaphragm and having separate outlets for the gases and liquids, substantially as described.

3. In electrolytic converter, the combination with the closed redox vessel having the anode and cathode terminals and an interposed diaphragm dividing the vessel into upper anode and lower cathode chambers, of an external, combined separator and vent-pipe having a U-shaped lower end opening through the bottom of the redox vessel into the cathode-chamber beneath the diaphragm, extending upwardly above the level of said diaphragm and having a free outlet for the gases, substantially as described.

4. In electrolytic converter, the combination with a redox vessel having anode and cathode terminals and an interposed diaphragm dividing the vessel, of an external, upright, separator and vent-pipe opening into the space beneath the diaphragm, and having a connection with the top of the vessel substantially as described.

5. In electrolytic converter, the combination with a redox vessel having anode and cathode terminals and an interposed diaphragm dividing the vessel, of an external, upright, separator and vent-pipe opening into the space beneath the diaphragm and having a branch intermediate its ends substantially as described.

699,965. CARBURIZER. ALEXIS L. HANSEN, Aymer Road, Canada. Filed May 24, 1901. Serial No. 61,604. (No model.)

Claim.—1. A carburizer comprising a tank provided with a false bottom terminating at one end within the tank to form an opening or passage, a partition having a perforated diffusing-section at the end of the false bottom and secured to the false bottom and the bottom of the tank, a radially-perforated diffusing-wall disposed wholly within the chamber formed by the false-bottom partition, a suitable oil-tight seal chamber, an air-pipe discharging into the chamber formed by said diffusing-wall, a tortuous circulating-passage within the tank, and a carburized-air outlet communicating with said passage, substantially as described.

2. A carburizer comprising a tank having means for diffusing air below the level of a hydrocarbon-bath, a helical partition within said tank and forming therein a corresponding circulation-passage and a central chamber, the flanges within the tank and on the helical partition, a top clamped to the tank, a top layer interposed between the flanges of the partition and the clamped top, and an outlet-pipe communicating with the central chamber, substantially as described.

3. A carburizer comprising a tank provided with a false bottom, a helical partition secured within the tank and to the false bottom thereof and forming the liquid-circulation space at the lower edge of said partition, a feed-plate secured to the partition, a feed-pipe supported by the feed-plate at the desired elevation, means for diffusing air below the false bottom and in the hydrocarbon-bath, and a carburized-air outlet communicating with the liquid-circulation space, substantially as described.

699,966. RAIL-JOINT. CHARLES E. HARR, East Palestine, Ohio. Filed Feb. 10, 1902. Serial No. 98,637. (No model.)

Claim.—In a rail-joint, the combination with the rails having openings formed in the sides of the base thereof in staggered relation to each other, of a chair comprising two sections each having base portions and carrying integral fish-plates extending to the under side of the rail-head, steps secured between the fish-plates and the base portions adapted to be received within said openings in the rail-base sides, an integral clamp extending under the base of the chair and having its ends bent to engage the upper portion of the chair, a pin engaging in the line for locking the movement of the chair, and a series of nuts and bolts extending through the fish-plates and the webs of the rails, substantially as described.

699,967. VEHICLE-CURTAIN ATTACHMENT. FREDERICK W. MANN, New York, N. Y. Filed Feb. 10, 1902. Serial No. 94,966. (No model.)

Claim.—1. In an attachment for vehicle-curtains, a sectional frame extending along the top and ends of the dashboard, and along the side of the body, then diagonally upward, means on the section for engaging the edge of a seat, a member engaging the under surface of the body and means for clamping the sections together.

2. In an attachment for vehicle-curtains, a frame comprising an approximately vertical standard with an upper and lower section, the former having an internal end to engage a seat, and the latter having a foot fitting under a body, an arm formed with the lower section, an extension hinged to the arm and a member carried by the arm for engaging the edge of a seat, as and for the purpose described.

3. In an attachment for vehicle-curtains, a frame comprising an approximately vertical standard with an upper and lower section, the former having an internal end to engage a seat, and the latter having a foot fitting under a body, an arm formed with the lower section, an extension hinged to the arm and a member carried by the arm for engaging the edge of a seat and a second member for engaging a supporting hook.

699,968. HYDRAULIC PRESS. E. McDONALD, Chicago, Ill. Filed Nov. 11, 1901. Serial No. 94,968. (No model.)

Claim.—1. As a new article of manufacture, a pair of cylinders having in combination a pair of levers, a pair of beams open at top, and a bow-spring having a horizontal intermediate portion with flat vertical faces, said intermediate portion being located in a horizontal plane above the horizontal plane of the beams and being located also in front of the vertical plane of the levers, said spring having beyond said intermediate portion portions which project forward and beyond these other portions which project downward in the vertical plane of the levers and enter the top of the beams, substantially as described.

2. As a new article of manufacture, a pair of cylinders having in combination a pair of levers, a pair of beams open at top, and a bow-spring having a horizontal intermediate portion with flat vertical faces whereby it is adapted to bend horizontally, while, at the same time, it is practically rigid vertically, said spring having also depending and portions that lie in the vertical plane of the levers and enter the beams at top, the spring being bent rearward and twisted between the extremities of said intermediate portion and the beams so as to bring the broad faces of the depending and portions into planes perpendicular with the vertical plane of said intermediate portion, substantially as described.

3. As a new article of manufacture, a pair of cylinders having in combination a pair of levers, a pair of beams open at top, a bow-spring having a horizontal intermediate portion with flat vertical faces whereby it is adapted to bend horizontally, while, at the same time, it is practically rigid vertically, said spring having beyond said intermediate portion portions that project forward and beyond these other portions that lie in the vertical plane of the levers and enter said beams at top, and rearwardly-extending cantilever guards secured to the posts, substantially as described.

4. As a new article of manufacture, a pair of cylinders having in combination beams open at top, a bow-spring having a flat intermediate portion which is straight when viewed from in front, said intermediate portion being located in a horizontal plane above the horizontal plane of the beams and in front of the vertical plane of the levers and being slightly curved as viewed from above, said spring having beyond said intermediate portion twisted portions extending first rearward, then inward and then downward, entering the top of the beams, substantially as shown and described.

699,969. PROCESS OF MAKING SPINEL. OWEN HARRIS, New York, N. Y. Filed Nov. 12, 1901. Serial No. 94,969. (No specimens.)

Claim.—1. An improved process for conducting also vapors to spin-

el, which consists in cooling the vapors in an atmosphere of water-gas, substantially as set forth.

2. An improved process for reducing also crystals over, which consists in subjecting the material to the pressure of heat to the reducing effect of water-gas, substantially as set forth.

3. An improved process for reducing also crystals over, which consists in subjecting the material to the reducing effect of heated water-gas, substantially as set forth.

4. An improved process of making spinel from also crystals over, which consists in subjecting the material to the pressure of heat to the reducing effect of water-gas, and in cooling the resulting also-vapors in an atmosphere of such gas, substantially as set forth.

5. An improved process of making spinel from also crystals over, which consists in subjecting the material to the reducing effect of heated water-gas, and in cooling the resulting also-vapors in an atmosphere of such gas, substantially as set forth.

6. An improved process of making spinel from also crystals over or also materials, which consists in subjecting a mixture of such material and coal in the presence of heat to the reducing effect of water-gas, and in cooling the resulting also-vapors in an atmosphere of such gas, substantially as set forth.

699,970. SHEATHING KNIFE. GEORGE R. FARRER, New Britain, Conn., assignor to F. & F. Cutler, New Britain, Conn., a Corporation of Connecticut. Filed Feb. 11, 1902. Serial No. 94,970. (No model.)

Claim.—1. A knife comprising a pair of leaves, one of said leaves having an undercut tapered cavity in the rear side thereof, and a detachable keeper-plate projecting into said cavity and secured thereto, said cavity being of an hour-glass shape, the keeper being adapted to engage in either end of said cavity.

2. A knife comprising a pair of leaves, one of said leaves having an undercut tapered cavity in the rear side thereof, and a detachable keeper-plate projecting into said cavity and secured thereto, screw-passages in said knife-leaves and in said keeper-plate, said passages in the leaf bearing said plate being sufficiently large to permit of the passage of the screw-head.

699,971. CURTAIN-POLE. GEORGE F. FARRER, Philadelphia, Pa. Filed Jan. 24, 1902. Serial No. 94,971. (No model.)

Claim.—1. In a device of the character described, a single pair of telescopically-mounted tubes having registering slots on their outer sides extending from a point in proximity to their outer ends through their other ends, the slot of the inner tube being enlarged adjacent to the outer end of the tube, with ornamental knobs secured to the outer ends of the tubes, and clips carrying integral balls adapted to pass through said enlarged portion of the slot and engage on the interior of the tubes, the outer tube having its end engaging the knob of the inner tube whereby the said enlarged opening of the latter is partially closed, substantially as described.

2. In a device of the character described, a single pair of telescopically-mounted tubes with registering slots, the slot of the inner tube being enlarged at its one end, clearing means carrying balls at their upper ends received in said enlarged portion and projecting through the slots from the interior of the pole, and knobs carried by the tubes, the knob of the inner tube being engaged by the lower end of the outer tube whereby the enlarged opening of the inner tube is partially closed to prevent the balls from leaving the interior of the tubes, substantially as described.

699,972. GLASS-FURNACE. JEAN P. FERRASS, Brooklyn, N. Y. Filed Jan. 15, 1902. Serial No. 94,972. (No model.)

Claim.—1. A glass-furnace provided with a central longitudinal partition forming the bottom of the furnace-chamber, a vertically-movable

plate mounted in the said bottom of the furnace-chamber, tracks or ways at the sides of the said bottom, a car mounted thereon, and means for raising and lowering said plate, said furnace-chamber being also provided at the front and thereof with doors and a central opening placed over said doors, and open at the bottom and grating placed therein, substantially as shown and described.

2. A glass-furnace open at both ends and provided with a central longitudinal partition forming the bottom of the furnace-chamber, a vertically-movable plate mounted in the top portion of said partition which forms the bottom of the furnace-chamber, tracks or ways at the sides of the furnace-chamber, and a car mounted thereon, a vertically-movable support on which said plate is placed, a lever pivoted to the support at the lower end of said support for raising and lowering the same, and a hollow central casing at the front and over the furnace-chamber, and the bottom of which is open and provided with grating, substantially as shown and described.

3. A glass-furnace provided with a central horizontal partition forming the bottom of the furnace-chamber, a vertically-movable plate mounted in the said bottom of the furnace-chamber centrally thereof, tracks or ways at the sides of the said bottom of the furnace-chamber and projecting forwardly and backwardly therefrom, and means for raising and depressing the vertically-movable plate, substantially as shown and described.

4. A glass-furnace provided with a central horizontal partition forming the bottom of the furnace-chamber, a vertically-movable plate mounted in the said bottom of the furnace-chamber centrally thereof, tracks or ways at the sides of the said bottom of the furnace-chamber and projecting forwardly and backwardly therefrom, and means for raising and depressing the vertically-movable plate, and cars mounted on said tracks or ways at the front and rear ends of the furnace, substantially as shown and described.

5. A furnace-chamber the bottom of which is provided with a cavity or recess, and a vertically-movable plate arranged centrally thereof, tracks or ways at the opposite side of said plate and extending through the furnace-chamber and projecting at each end thereof, a burner-ports at one side of said chamber and communicating therewith, and means for supplying fuel to said ports, substantially as shown and described.

6. A gas-furnace, the bottom of the chamber of which is provided with a cavity or recess, a vertically-movable plate placed in said cavity or recess, means for raising and lowering said plate, a vertically-arranged casing supported over the front of the furnace-chamber and open at the bottom and provided with front openings, and means for supporting glass therein, substantially as shown and described.

7. A gas-furnace, the bottom of the chamber of which is provided with a cavity or recess, a vertically-movable plate placed in said cavity or recess, means for raising and lowering said plate, a vertically-arranged casing supported over the front of the furnace-chamber and open at the bottom and provided with front openings, and means for supporting glass therein, said furnace-chamber being also provided at one side with a fuel-ports in communication therewith and means for supplying fuel thereto, substantially as shown and described.

699,973. SAND-DRILLING MACHINE. ARTHUR FARRER, Vienna, near Baden, Germany. Filed Oct. 25, 1901. Serial No. 94,973. (No model.)

Claim.—1. In a sand-drilling machine, the combination, of a substantially-supported rectangular frame having longitudinally-arranged beams thereon, said beams being provided with ways, means for laterally adjusting one of said beams, and a sand-cask supported on said beams at one end of the machine, substantially as set forth.

2. In a sand-drilling machine, the combination, of a rectangular frame having a stationary beam and a movable beam, ways provided on said beams, means for laterally adjusting said movable beam, and rest-standards secured at one end of the machine, substantially as set forth.

3. In a sand-drilling machine, the combination, with a rectangular frame, of a stationary beam and a movable beam, said beams being pro-

vided with ways, means for laterally adjusting said movable beam, and stationary and adjustable rest-standards secured on said beams and suitably-provided brackets, said adjustable standards being secured on said brackets, substantially as set forth.

4. In a sand-drilling machine, the combination, with a rectangular frame, of a stationary beam and a movable beam, said beams being provided with parallel ways, means for laterally adjusting said movable beam, stationary and adjustable standards of angle-iron, and clotted brackets secured at one end of the frame to the ways with said beams having said adjustable standards adjustably secured thereon, substantially as set forth.

5. In a sand-drilling machine, the combination, with parallel beams provided with suitable ways, of a frusto-conical engaging roll on each beam, a cylindrical roll adjacent to said frusto-conical roll, and means for actuating the same, substantially as set forth.

6. In a sand-drilling machine, the combination, with beams having parallel ways, of a frusto-conical engaging roll vertically mounted on each of said beams, a cylindrical roll also mounted on each beam adjacent to said frusto-conical roll, and means for imparting similar rotary motion to said rolls, substantially as set forth.

7. In a sand-drilling machine, the combination, with parallel beams provided with ways, of a mill-wheel at one end of the machine, feed-rolls on each beam adjacent said wheel, and means for actuating said feed-rolls, substantially as set forth.

8. In a sand-drilling machine, the combination, with parallel beams provided with ways, of suitable means fed in said ways, a suitably-supported sand-containing hopper, and means for vertically adjusting said sand-containing hopper, substantially as set forth.

9. In a sand-drilling machine, the combination, of a rectangular frame supporting longitudinally-arranged beams, said beams being provided with ways, a mill-wheel on said ways, a sand-containing hopper supported on said frame, a movable partition in said hopper, and a yoke-shaped support for said partition carried on said beams, substantially as set forth.

10. In a sand-drilling machine, the combination, of suitably-supported beams, a sand-containing hopper, supports for said hopper, standards on said beams having ways for guiding said supports, screw-clamps carried by said standards engaging said supports, means for simultaneously operating said screw-clamps for adjusting the hopper, said hopper having a converging mouth, an adjustable lip for said mouth, and a resilient stirrer inclined rearwardly from said mouth, substantially as set forth.

699,974. APPARATUS FOR DRILLING, TREATING, AND DELIVERING SAND. CHARLES J. REILL, Syracuse, Ind., and Spencer B. Bortney, Sandusky, Ohio, assignors to the Sandusky Portland Cement Company, Sandusky, Ohio, a Corporation of West Virginia. Filed July 28, 1901. Serial No. 94,974. (No model.)

Claim.—1. In combination, a hopper, and, supported upon it, a driving mechanism, a pump into which the material raised by the drive is delivered, two air-tight tanks, valve pipes through which the products of the pump may be delivered into said tanks respectively, a compressed-air apparatus, and valve pipes connecting it with the two tanks respectively, valve discharge-pipes for said tanks, and a suitable pipe connected with said discharge-pipes and extended therefrom to the shore, substantially as and for the purpose specified.

2. In combination, a hopper, and, supported upon it, a driving mechanism, a pump into which the material raised by the drive is delivered, two air-tight tanks, valve pipes through which the products of the pump may be delivered into said tanks respectively, a compressed-air

apparatus, and valves connecting it with the two tanks respectively, a valve-discharge-pipe for said tanks, and a flexible pipe connected with said discharge-pipe and extended thence to the shore, a branch-pipe to which the shore end of said flexible pipe is connected, valves in said branch, and receiving-tanks into which said branches respectively discharge, substantially as and for the purpose specified.

3. In combination, a boat, and, supported upon it, dredging mechanism, a pag-mill into which the material raised by the dredge is delivered, two air-tight tanks, valves through which the products of the pag-mill may be delivered into said tanks respectively, a compressed-air apparatus, and valves connecting it with the two tanks respectively, valves discharge-pipes for said tanks, an electric motor and driving mechanism connecting the same with the dredging mechanism, the pag-mill, and the compressed-air apparatus, a flexible pipe, to which both of said discharge-pipes are connected, and which extends to the shore, flange to which said flexible pipe is connected, and conductor-wires supported by said flexible pipe and extending from the shore to the motor on the boat, substantially as and for the purpose specified.

4. In combination, a boat, two air-tight tanks on said boat, each having a valve-controlled inlet-pipe and a valve-controlled outlet-pipe, mechanism for simultaneously operating the valves in all of said inlet and outlet pipes, a flexible pipe connected with said outlet-pipes and extended to the shore, an air-compressor upon said boat, and two valve-controlled pipes connecting said air-compressor with said tanks respectively, substantially as specified.

699,975. ENVELOPE-FEEDING ATTACHMENT FOR TYPE-
WRITERS. RALPH E. RYNDEN, Hartford, Ct. Filed Mar. 21, 1900.
Serial No. 10,968. (No model.)

Claim.—1. In an envelope-feeding attachment for type-writing machines, the combination with the carriage of the machine, of device adapted to be operated when the carriage is shifted for ejecting an envelope therefrom, substantially as described.

2. In an envelope-feeding attachment for type-writing machines, the combination with the carriage of the machine, of device connected with and operated by said shifting means for ejecting an envelope from the carriage, substantially as described.

3. In an envelope-feeding attachment for type-writing machines, the combination with the carriage of the machine, of device adapted to be operated by the shifting movement of the carriage to feed an envelope to the machine, substantially as described.

4. In an envelope-feeding attachment for type-writing machines, the combination with the carriage of the machine, comprising a platen-roller and a holding-roller, of device adapted to be operated when the carriage is shifted for operating the holding-roller from the platen-roller, substantially as described.

5. In an envelope-feeding attachment for type-writing machines, the combination with the carriage of the machine, comprising a platen-roller

and a holding-roller, of means for shifting the carriage and device connected with and adapted to be operated by said shifting means for operating the holding-roller from the platen-roller, substantially as described.

6. In an envelope-feeding attachment for type-writing machines, the combination of device for ejecting an envelope from the machine and device simultaneously operating to feed a fresh envelope into position for printing, substantially as described.

7. In an envelope-feeding attachment for type-writing machines, the combination with the carriage of the machine, of a carrier, a supply-holder and means for feeding the envelope separately from the holder to the carrier, substantially as described.

8. In an envelope-feeding attachment for type-writing machines, the combination with the carriage of the machine and an envelope-supply holder of a carrier located below the holder and intermediate of the holder and the carriage, substantially as described.

9. In an envelope-feeding attachment for type-writing machines, the combination with the carriage of the machine, and a holder for a supply of envelopes, of a carrier located intermediate of the carriage and holder and traveling with the carriage, substantially as described.

10. In an envelope-feeding attachment for type-writing machines, the combination with the carriage of the machine, of a holder located behind and above the carriage, and a carrier arranged between the holder and carriage and adapted to receive the envelope from the holder and feed them singly to the machine, substantially as described.

11. In an envelope-feeding attachment for type-writing machines, the combination with the carriage of the machine, of a holder carrying a supply of envelopes, a carrier arranged between the holder and the carriage of the machine, and device for feeding the first envelope from the supply to the carrier, substantially as described.

12. In an envelope-feeding attachment for type-writing machines, the combination with the carriage of the machine, an envelope-supply holder and a carrier located between the holder and the carriage, of device for feeding an envelope from the supply to the carrier and device for feeding the envelope from the carrier to the carriage, substantially as described.

13. In an envelope-feeding attachment for type-writing machines, the combination with the carriage of the machine, an envelope-supply holder and a carrier arranged between the carriage and the holder, of device for feeding an envelope from the holder to the carrier, device for ejecting an envelope from the carriage, and device for feeding an envelope from the carrier into position for printing, substantially as described.

14. In an envelope-feeding attachment for type-writing machines, the combination with the carriage of the machine, an envelope-supply holder and a carrier arranged between the carriage and holder, of device for feeding an envelope from the holder to the carrier, from the carrier to the carriage and finally ejecting the envelope from the carriage, all of said devices being operated simultaneously when the carriage is shifted, substantially as described.

15. In an envelope-feeding attachment for type-writing machines, the combination with the carriage of the machine, a holder for a supply of envelopes and a carrier traveling with the carriage of means for shifting the carriage, and device for feeding an envelope from the holder to the carrier, device for feeding an envelope from the carrier into position for printing and at the same time ejecting the previously-printed envelope, said device being actuated when the carriage is shifted, substantially as described.

16. The combination with a type-writer, of an envelope-feeding attachment comprising a holder for a supply of envelopes, and main and temporary holding-dogs operating to release the first envelope in the pile and allow the same to drop freely from the holder, substantially as described.

17. In an envelope-feeding attachment for type-writing machines, a holder for a supply of envelopes, a main holding-dog normally engaging the first envelope in the supply to keep the envelope from falling out of the holder and a temporary holding-dog, and device intermediate of the carriage of the machine and said dogs for operating the same whenever the carriage is shifted, substantially as described.

18. In an envelope-feeding attachment for type-writing machines, a holder for a supply of envelopes, a main holding-dog and a temporary holding-dog operating on said envelope-supply, device supporting said dogs, a bell-crank lever adapted to rotate said device to raise the temporary holding-dog into contact with the envelope-supply and depress the main holding-dog, and a device carried by the carriage for returning the bell-crank lever, substantially as described.

19. The combination with a type-writing machine, of a carriage, a feeding attachment comprising the combination with a carrier traveling with the carriage, of means adapted to support an envelope temporarily in the carrier and adapted when withdrawn, to permit the envelope to drop through the carrier, substantially as described.

20. In an envelope-feeding attachment for type-writing machines, the combination with the carriage supported on and traveling with the carriage

of the machine, of supporting-arm adapted to support an envelope in the carrier and means for automatically operating said supporting-arm when over the carriage of the machine is shifted, substantially as described.

21. In an envelope-feeding attachment for type-writing machines, the combination with a carrier, of pivotal arms normally covering the movement of an envelope through the carrier and adapted to be operated to release the envelope whenever the carriage is shifted, substantially as described.

22. In an envelope-feeding attachment for type-writing machines, the combination with shifting means, of a carrier, device for temporarily covering the movement of an envelope through the carrier and connection between the shifting means and said covering device for operating the latter to release the envelope, substantially as described.

23. In an envelope-feeding attachment for type-writing machines, the combination with a platen-roller and means for revolving the same to open lines of printing, of device normally arranged in position for limiting the feeding of the envelope and means connected with the device for revolving the platen-roller adapted to throw the stop-guide device out of the way of the feeding of the envelope, substantially as described.

24. In an envelope-feeding attachment for type-writing machines, the combination with a roller-platen, of a rack-shaft located in front of the platen, stop-guides rigidly mounted on said rack-shaft and provided with forwardly-turned upper ends adapted to limit the initial feeding of the envelope around the platen in position for printing, a lever device for revolving the roller-platen for line-spacing, and an arm carried by said lever device and adapted to rock the stop-guides shaft so as to release the stop-guides from engagement with the envelope when the latter is fed through the machine to receive a second line of printing, substantially as described.

25. The combination with a type-writing machine, of a feeding attachment comprising a holder for a supply of envelopes, a main holding-dog normally in engagement with the envelopes, and a temporary holding-dog to be engaged with the envelope behind the first envelope to hold them in place while the first envelope is being fed from the holder, substantially as described.

26. In an envelope-feeding attachment for type-writing machines, the combination with a carriage, of shifting means connected with the carriage a platen-roller and a holding-roller carried by the carriage and device connected with the shifting means for simultaneously ejecting the addressed envelope from the machine and arranging a fresh envelope in position for printing, substantially as described.

27. In an envelope-feeding attachment for type-writing machines, the combination with a carriage, of shifting means connected with the carriage a platen-roller and a holding-roller carried by the carriage and device adapted to be operated by the shifting means for drawing the holding-roller away from the platen-roller and revolving the platen-roller to eject the addressed envelope and arrange a fresh envelope in position for printing, substantially as described.

28. In an envelope-feeding attachment for type-writing machines, the combination with a carriage, of a platen-chest mounted thereon and carrying the platen-roller, a pulley on said platen-chest, a pull-cord for shifting the carriage and hooked around the pulley on the platen-chest to revolve said chest when the carriage is shifted and means for limiting this rotation of the platen-chest, substantially as described.

29. In an envelope-feeding attachment for type-writing machines, the combination with a carriage, of a platen-chest carrying a roller-platen, a ratchet-wheel rigidly mounted on said chest and provided with an elongated hub, a pulley loosely mounted on said hub and carrying a pawl arranged to engage the teeth of the ratchet-wheel and a pulley cord device for shifting the carriage and connected with said pulley to revolve the platen at the same time that the carriage is shifted, substantially as described.

30. In an envelope-feeding attachment for type-writing machines, the combination with a carriage, of a platen-chest mounted thereon and provided with a roller-platen, a ratchet-wheel rigidly mounted on said chest and having an elongated hub, a pulley loosely mounted on said hub and provided with a pawl engaging the teeth of the ratchet-wheel, a pull-cord for shifting the carriage and operating over the pulley to revolve the platen as the carriage is shifted, a stop-plate carried by the pulley, a rigid stop-bar adapted to be engaged by the stop-plate and a spiral spring for returning the pulley to its original position after the carriage has been shifted, substantially as described.

31. In an envelope-feeding attachment for type-writing machines, the combination with a roller-platen and a holding-roller, of a pull-cord and device adapted to be operated by the pull-cord for withdrawing the holding-roller away from the platen-roller and revolving the platen-roller, substantially as described.

32. In an envelope-feeding attachment for type-writing machines, the combination with a roller-platen and a holding-roller, of a pull-cord shifting device and connection intermediate thereof and the roller-platen and holding-roller adapted to be operated when the cord is pulled to draw the holding-roller away from the platen-roller and revolve the platen-roller, substantially as described.

33. In an envelope-feeding attachment for type-writing machines, the combination with a platen-roller, of a holding-roller, a lever, connection between said lever and the holding-roller, a pull-cord adapted to shift the lever on its pivot to draw the holding-roller away from the platen-roller, substantially as described.

34. In an envelope-feeding attachment for type-writing machines, the combination with carriage carrying the platen-roller and a holding-roller, of a lever pivotally mounted on the carriage and connected at one end with, and adapted to draw the holding-roller away from the platen-roller and a pull-cord device adapted to swing said lever on its pivot at the same time as it shifts the carriage, substantially as described.

35. In an envelope-feeding attachment for type-writing machines, the combination with a carriage carrying a platen-roller and holding-roller, of a lever pivotally mounted on the carriage and having one end connected with the holding-roller, a swinging arm on the carriage, a cord connected with said swinging arm and the lever and means for pulling on said cord to shift the lever on its pivot, substantially as described.

36. In an envelope-feeding attachment for type-writing machines, the combination with the carriage carrying a platen-roller and a holding-roller, of a lever pivotally mounted on the carriage, a rack-bar, a stop-pawl, pivotally mounted on one end of said lever, a pivoted arm on the carriage, a cord connected to said pivoted arm and the stop-pawl and means for swinging the arm to throw the stop-pawl into engagement with the rack-bar and swing the lever on its pivot, substantially as described.

37. In an envelope-feeding attachment for type-writing machines, the combination with a carriage carrying a platen-roller and a holding-roller, of a lever pivotally mounted on the carriage, a stop-pawl pivoted to one end of the lever, a rack-bar, a swinging arm on the carriage, a cord connecting said swinging arm with the stop-pawl, and a pull-cord adapted to be operated to shift the carriage and at the same time cause the stop-pawl to engage the rack-bar and the lever to swing on its pivot to carry the holding-roller away from the platen-roller and partially revolve the platen-roller, substantially as described.

38. In an envelope-feeding attachment for type-writing machines, the combination with a carriage carrying a platen-roller and a holding-roller, of a carrier supported on the carriage, temporary supporting-arm mounted on the carrier, a lever pivoted on the carriage and a pull-cord for shifting the carriage, partially revolving the platen-roller, swinging the lever on its pivot, drawing the holding-roller away from the platen-roller and throwing the supporting-arm away from the carrier, substantially as described.

39. The combination with a type-writing machine, of a feeding attachment comprising a holder for a supply of envelopes, a main holding-dog provided with a detent and normally retaining the envelopes in the holder, and a temporary holding-dog operating through the detent of the main holding-dog and adapted to hold all the envelopes in the holder except the first envelope, while the main holding-dog is depressed to permit the first envelope to be fed from the holder, substantially as described.

40. The combination with a type-writing machine, of a carriage; an envelope-feeding attachment comprising the combination with a carrier traveling with the carriage, of supporting device for temporarily arresting the movement of an envelope through the carrier, substantially as described.

699,976. ATTACHMENT FOR UNITING METAL OR WOOD
BEAMS. JAMES T. REINHARD, New York, N. Y. Filed Aug. 12, 1901.
Serial No. 73,694. (No model.)

Claim.—1. As a new article of manufacture, a wire clip for uniting one small beam to another formed with two extended tongues adapted to cooperate with the smaller beam to compel the clip to grip the larger beam and flexibly hold the smaller beam closely thereto, substantially as described.

2. The combination of a containing-beam, expanded beam and a spring-metal clip, the clip being extended along the upper surface of the expanded beam and by the wedging action of each beam between the extended ends to the clamp thereof compelling a grip to be taken upon the flange of the containing-beam, substantially as described.

699,977. NARROW-WARE LOOM. EMERY EISEL, Jr., Philadel-
phia, Pa. Filed Jan. 23, 1905. Serial No. 61,166. (No model.)

Claim.—1. In combination with a beam, an upper shuttle-carrying block, a lower shuttle-carrying block mounted on said beam and a plate common to said shuttle-blocks and situated between said blocks and the beam, a projection on said plate and an adjusting member upon one of said blocks adapted to engage said projection.

2. In combination with a beam, an upper shuttle-carrying block, a lower shuttle-carrying block mounted on said beam and a dotted plate situated between said blocks and beam and provided with a projection, means passing through said lower block and plate for supporting the latter and an adjusting member upon said lower block adapted to engage with said projection.

3. The combination of a beam, an upper shuttle-carrying block, a lower shuttle-carrying block mounted on said beam, a plate provided with a projection thereon, situated between said blocks and beam, and an adjusting member upon said lower block having a flaring head engaging said projection.

4. The combination with a beam, of an upper shuttle-carrying block, a plate secured to said upper block and having a slot in its lower portion, a projection on said plate, the latter being situated between said blocks and beam, means for securing the lower shuttle-carrying block to said beam, and an adjusting member upon said lower block, said adjusting member having a flaring head engaging said projection, whereby said upper and lower blocks can be moved toward and away from each other according to requirements.

5. In combination with a beam, an independent upper shuttle-carrying block, an independent lower shuttle-carrying block, both of which are suitably supported on said beam, and a plate common to said shuttle-blocks and secured to one of said blocks, and an adjusting member upon the other of said blocks adapted to engage with said plate for operating the same to adjust the said blocks.

699,978. HORIZONTAL SOUNDER. EMERY RECOVER, New York, N. Y. Filed Jan. 20, 1901. Renewed Sept. 24, 1904. Serial No. 70,412. (No model.)

Claim.—1. A musical sounder having beveled flaps extending to its lateral edges, the said edges being also beveled at inclinations differing from those of the flaps, and provided at its respective edges and beyond the limits of the flaps with divided or test ribbons parallel with the adjacent edges, said ribbons having their flaps oblique to the face of the body, substantially as set forth.

2. A musical sounder comprising a body having beveled flaps extending to its lateral edges, and provided with a ribbon or ribbons at each of its lateral edges, said ribbons being divided or test and having their flaps oblique to the face of the body, substantially as set forth.

3. A musical sounder comprising a hollow body A, with inclined flaps a', and ribbons B, at its lateral edges, said ribbons being divided or test and having their flaps oblique to the general plane of the body, substantially as set forth.

699,979. METHOD OF PRESERVING MEAT. HERMAN VAN
Nest, Stuttgart, Germany. Filed Mar. 22, 1902. Serial No. 90,690. (No specimens.)

Claim.—1. A method of preserving meat which consists in impregnating it with an infusion of tea.

2. A method of preserving meat which consists in impregnating it with a brine containing tea.

3. A method of preserving meat which consists in adding an infusion of tea to the preserving liquid.

699,980. TABLE-TURNER ME. JOHN GARDNER, Liverpool, Eng-
land. Filed Feb. 12, 1900. Serial No. 90,694. (No model.)

Claim.—A table-turner set, having the combination of a horizontal metallic bar bent upward at the ends to form posts, fast secured to said horizontal bar, and a flexible network secured at each end to said bent part by said uprights, substantially as described.

699,981. ARCH-BAR. THOMAS C. SALVETER, St. Louis, Mo.
Filed Sept. 14, 1901. Serial No. 70,690. (No model.)

Claim.—1. An arch-bar, comprising a curved upper member, a lower member having its ends substantially parallel with the said upper member, and connected therewith by integral webs and the middle of the

lower member extending below the said upper member, posts connecting the upper and lower members, and a spring-act supported above the lower member and formed integral therewith and with the said posts.

2. The improved arch-bar, comprising an arched upper member, a lower member, having its ends substantially parallel with the upper member and connected thereto by integral webs, divergent extensions 4 integral with the lower member, integral posts 5 connecting the divergent parts 4 of the lower member with the upper member, the horizontal part 6 of the lower member formed integral with the lower end of said posts, and a spring-act supported between the posts above the said part 6.

3. The improved arch-bar, comprising an arched upper member, a lower member having its ends extended horizontally below the ends of the upper member and connected therewith by integral webs, posts integral with the upper member, a spring-act integral with the lower ends of said posts, integral posts 4 of the lower member connecting the lower ends of the said posts with the horizontal portions of the lower member and with the upper member, and reinforcing-flanges integral with said members to give additional strength.

699,982. DISSEMINATING DEVICE FOR SHEEP-SHEARERS. JAMES
F. SHAWNEY and CHARLES L. LOR, Newark, N. J. Filed May 21, 1901.
Serial No. 68,881. (No model.)

Claim.—1. A disseminating device for disinfectants, comprising an inverted-cup-like body portion adapted to cover the perforated disinfectant plate of a sink, an inner receptacle for disinfectant operably connected to said body portion, and a central stem on said receptacle adapted to enter a perforation of the disinfectant-plate and support the device.

2. The basic-disseminating device for disinfectants, consisting of a body portion in the form of an inverted cup provided with a handle A, a receptacle for disinfectant attached to the inner walls of said body portion and being perforated, and a resilient stem f, projecting downwardly from said receptacle to enter the sink-drain.

3. In a disseminating device for disinfectants, the combination of a bell-shaped body portion adapted to be held with its mouth over the disinfectant, a perforated receptacle within said body portion and a stem comprising resilient wires spread apart or bowed between their extremities and united at their projecting extremities distant from the body portion and receptacle, substantially as set forth.

4. The combination of the body portion d, having the interior corner recess d', a disinfectant-receptacle e, adapted to enter at its upper edges said recess, legs i, on the receptacle and supporting rest f', on the body portion for connecting said parts, and a stem f, depending from the said receptacle and formed of a plurality of wires bowed apart intermediate of their ends.

5. The combination with the bell-shaped cover, of a resilient stem projecting down below the bottom edge of said cover, at, or approximately at, the axial center of said cover, said stem comprising a series of bent wires united at their projecting extremities to enter together through a small perforation of a disinfectant-plate, substantially as set forth.

699,983. HOLDER FOR TOOTH-BRUSHES AND TOOTH-POW-
DER. BENJAMIN C. H. SHAWNEY and CARL F. SHAWNEY, Philadelphia, Pa.
Filed Oct. 12, 1901. Serial No. 70,690. (No model.)

Claim.—1. A holder for a tooth-brush and a tooth-powder comprising a rectangular receptacle formed of a base of approximately the length of the tooth-brush and of a width approximately equal to the depth of

the bristle portion thereof, and having upwardly-projecting walls of a height at least equal to the width thereof, a tooth-powder-containing compartment formed in the said rectangular receptacle at one end thereof and projecting rearwardly beyond the transverse center thereof whereby the rear or inner wall of the compartment forms with the rear or outer wall of the main holder a narrow longitudinal compartment continuous with the main or opposite end portion of the compartment comprised by the receptacle, and ranging parallel with the said rear wall of the holder and in such relation thereto as to operate in connection therewith to hold the handle of the brush whereby to retain the same in the holder against displacement; and the said tooth-powder-containing compartment being of a length to leave a space between the bristles of a tooth-brush and the inner end of the compartment for the entrance of a finger beneath the neck of the brush; and means operating in connection with the tooth-powder-containing compartment and the outer wall of the holder whereby to close the said tooth-powder-containing compartment only, leaving the main or brush-holding compartment open.

2. A holder for a tooth-brush comprising a receptacle formed of a rectangular base of a length approximately equal to that of an ordinary tooth-brush and of a width approximately equal to the depth of the bristle portion thereof and formed with upwardly-projecting walls in height at least equal to the width of the brush and adapted to receive the entire brush within the same when the handle of the brush is placed in contact with one of the longitudinal walls of the said receptacle; a tooth-powder-containing compartment formed of a longitudinal partition ranging within the main receptacle or compartment and at one end thereof parallel with the said longitudinal wall of the holder and rearwardly of the transverse center of the holder and in such relation to the said longitudinal wall as to operate in connection with the said longitudinal wall to hold the handle of the brush whereby to retain the same in the holder against displacement, the said partition being secured to one end wall of the holder and to the base and ranging longitudinally to a point appreciably below the position of the bristles in the operative position of the brush in the holder whereby a finger may be inserted between the said bristles and the end of the partition beneath the neck of the brush to remove the same from the holder; the inner end of the said partition being turned around to form a semi-circular or rounded end wall for the tooth-powder-containing compartment, and being secured to the base and to the front wall of the main receptacle and the said partition, and its rounded end or extension being of equal height with the walls of the brush-holder; and a lid for the tooth-powder-containing compartment only, the said lid being hinged to the partition and extending to the front wall of the holder and provided with a longitudinal flange adapted to connect the said lid to the said front wall, means upon the said flange and upon the said front wall for fastening the lid down, a flange upon one end of the lid overlapping the outer end of the main receptacle and downwardly-projecting corner-lugs upon the opposite inner end of the lid engaging the rounded or semi-circular end or extension of the partition.

699,984. CARRIAGE-LOCK. ADOLPHUS C. SMITH, New Haven, Conn. Filed Oct. 16, 1901. Serial No. 70,690. (No model.)

Claim.—1. A carriage-lock having a substantially spherical operating-hub, whereby said hub may have universal movement in its casing for the purpose specified.

2. A carriage-lock having hub-openings in its plate made of least diameter on the outer side and flaring inward, and a substantially spherical hub to correspond with the openings, whereby said hub may have universal movement relatively to said openings, for the purpose specified.

3. A carriage-door lock, substantially as shown and described, having a hub provided with a spindle-opening, said hub being mounted for universal movement to adapt it to receive a spindle of other than a right angle to the plane of the lock.

699,985. MACHINE FOR WEAVING CROSS-WIRES IN PIGGON.
HAROLD STEIN and HARRY BROWN, Columbus, Ohio. Filed Apr. 27,
1901. Serial No. 67,000. (No model.)

Claim.—In a machine for weaving cross-ribs in tissue, the combination with a framework comprising vertical frame-standards and spools 6 having enlarged heads journaled in said frame-standards, said heads having peripheral notches 11, the shafts of said spools being tubular and a gear connection between the outer ends of said shafts, of a reel-frame 12 having journaled therein a wire-carrying spool, said frame 12 having transverse 14 and 15, the latter being tubular, said transverse adapted to engage oppositely-located notches of the spool-heads 4 and 5, and means for directing said transverse from the notches of one pair of heads into the notches of an adjacent pair, substantially as specified.

699,986. CAR-FENDER. WILLIAM SULLIVAN, St. Louis, Mo. Filed July 14, 1901. Serial No. 95,577. (No model.)

Claim.—In a car-fender, a fender pivoted to the car body at its rear end; an arm 5 extending rearwardly from the center of the fender; the frame 7 hinged to the lower end of the car-body the roller 8 mounted in said frame, and engaging the arm 5 as required to hold the front end of the frame 7; a spring 9 holding said frame in its vertical position, said frame being mounted to swing backwardly against the tension of the spring as required to carry the roller 8 out of engagement with the arm 5 and allow the arm 5 to swing upwardly, then depressing the forward end of the fender; the rod 10 connected to the lower end of the frame 7 and extending forwardly; the sleeve 12 upon the forward end of the rod 10; the rod 11 connected to the forward end of the fender, the forward end of said rod being bifurcated; the secondary fender or frame 14 mounted upon the forward end of said rod and projecting beyond the first fender, so that when the secondary fender strikes an obstruction on the track, the frame 7 will be operated to allow the arm 5 to be lifted, then depressing the forward end of the fender, substantially as specified.

699,987. POCKET IMPLEMENT. JAMES TAYLOR and JOHN ROBERTSON, Lancaster, England. Filed Sept. 12, 1903. Serial No. 75,516. (No model.)

Claim.—A tool or implement or use when described comprising an elongated body portion, V-shaped in cross-section and pointed at one end, the lower walls of the sides thereof being provided with rounded corners, and a head or plate pivoted to the larger end thereof, substantially as shown and described.

699,988. CATTLE-STALL. JAMES B. TIERNEY, WILLIAM TIERNEY, and FRANKLIN H. MONTGOMERY, Chardon, Tex. Filed Oct. 21, 1903. Serial No. 79,495. (No model.)

Claim.—In a cattle-stall, a series of posts suitably pivoted at their lower ends, a second series suitably pivoted at their lower ends and acting in conjunction with the first-named series, links pivoted to the tops of the posts and pivoted together in pairs, upwardly-extending links pivoted to the intermediate pair of links, a lever for elevating and depressing the upwardly-extending links, and boards and rails connecting the posts to form opposite sides whereby the movement of the intermediate posts will be conveyed to the end posts, as and for the purpose described.

699,989. SHOULDERING BLOCK. FRANK E. VANHORN, Watertown, Conn., assignor of one-half to John Meyer, Watertown, Conn. Filed Oct. 17, 1901. Serial No. 75,909. (No model.)

Claim.—1. In a shoe-lacing device, the combination with a lacing-rod, of an annular depending flexible apron for the shoe covering the heel and adapted to hold the lacing-rod in position to pass thereby for engagement with the said heel.

2. A shoe-lacing device comprising a steel having an annular projecting yieldable extension secured thereto covering the entrance to the heel and provided with suitable notches in its peripheral forming string pockets.

3. A shoe-lacing device comprising a steel having an enlarged head integral therewith, a covering for said head with a depending flexible apron including the entrance to the heel.

699,990. SHOULDERING BLOCK. FRANK E. VANHORN, Watertown, Conn., assignor of one-half to John Meyer, Watertown, Conn. Filed Oct. 17, 1901. Serial No. 75,909. (No model.)

Claim.—1. A shoe-lacing device comprising an eyelet and heel portion, a protector made of flat spring material and secured to the base of said heel and normally extending upward across the opening of the heel and having its end substantially at the edge of the heel and designed to automatically spring open or close with the passage of the shoe thereunder.

2. A protecting device for a shoe-lacing heel consisting of a sheet-metal ring-like part having an upwardly-deflecting flexible extension fitted into the base portion of the heel so that said extension will normally close the mouth of the heel but will yield in either direction with the insertion or removal of the foot.

699,991. COOKING-STOVE. BENJAMIN A. VAUGHN, Curing, Cal. Filed Feb. 3, 1903. Serial No. 92,492. (No model.)

Claim.—In a cooking-stove, the combination, of the oven, the warming-chamber having shelves with openings for the passage of air, a fire-pot and ash-box located between the oven and warming-chamber, smoke-passages extending around the oven and under the warming-chamber, a smoke-pipe communicating with the smoke-passages and extending up at the outer side of the warming-chamber, a damper in the smoke-passage above the oven, and a smoke-passage above the warming-chamber having a damper or a damper in at the upper end of the warming-chamber leading into the smoke-pipe, a door to the warming-chamber, and a wheel or damper at the lower end of the door; the damper, a, c, and a having operating-rods extending through the front of the stove, as herein shown and described.

699,992. HOISTING APPARATUS. SAMUEL E. WALSH, Montreal, Pa. Filed Oct. 28, 1903. Serial No. 92,416. (No model.)

Claim.—1. A rotary element having two sets of driving connections, one set including worm-gearing, and connection between the two sets, said connections including a plurality of clutches, each having lost motion; substantially as described.

2. A rotary element having spur-gear driving connections and worm-gear driving connections, the spur-gear having a plurality of connections with the worm-gear, said connections including at least two clutches having lost motion; substantially as described.

3. A rotary element having spur-gearing driving connections, one of the shafts of the spur-gears having lost-motion clutch connection with a worm-gear, mechanism for driving the other element of the worm-gear, and means for adjusting the amount of lost motion in the clutch; substantially as described.

4. A rotary element having spur-gearing driving connections, worm-gearing driving connections, the shafts of the spur-gears being provided with lost-motion clutch connections with the worm-gearing elements, one at least of said lost-motion connections being adjustable; substantially as described.

699,993. STAIRWAY. FREDERICK W. WHEEL, Danbury, Pa. assignor of one-half to Benjamin F. Keller, Danbury, W. Va. Filed Feb. 25, 1903. Serial No. 91,570. (No model.)

Claim.—1. A sectional rail adapted to support or guard a stairway composed of a series of similar sections provided with locking devices whereby they are interlocked together.

2. A sectional rail for supporting or guarding a stairway composed of a series of similar one-shaped interlocked sections having beveled joints.

3. As an article of manufacture a section for a rail adapted to support or guard a stairway consisting of a block having beveled ends provided with parts of two locking devices.

4. As an article of manufacture a block adapted to constitute a section

of a stairway string-board and provided at its opposite ends with parts of two locking devices, said block having horizontal ends in different planes and an intermediate vertical end.

5. As an article of manufacture a block adapted to constitute a section of a stairway string-board and provided at its opposite ends with parts of two locking devices, said block being step-shaped along its upper edge and inclined along its lower edge, said lower edge being provided with a rabbet.

6. A sectional rail for a stairway comprising a series of similar sections provided with concealed locking devices whereby they are interlocked together.

7. As an article of manufacture a block adapted to constitute a section of a stairway string-board having a vertical flange at its lower end and a vertical flange at its upper end, one of said flanges being provided with a plate having slots enlarged at their upper ends and the other of said flanges being provided with a plate having beveled ends.

8. As an article of manufacture a block adapted to constitute a section of a stairway supporting rail, said block being step-shaped along its upper edge and inclined along its lower edge and provided with vertical flanges at its opposite ends, one of said flanges being provided with a plate having slots enlarged at their upper ends and the other of said flanges being provided with a plate having beveled ends.

699,994. VEHICLE-WHEEL. PAUL E. WHEEL, Indianapolis, Ind., assignor to White Steam Wagon Company, Indianapolis, Ind., a Corporation of Indiana. Filed Nov. 20, 1901. Serial No. 94,116. (No model.)

Claim.—1. A vehicle-wheel having its central portion formed integrally of cast metal, and comprising a central hollow hub, a series of spokes V-shaped in cross-section, a peripheral rim surrounding said spokes at their outer ends, and a central disc connected to said rim, all substantially as shown and described.

2. The combination, in a vehicle-wheel, of an integral central portion comprising a hub, spokes and rim, and a tire composed of sections secured to the outer surface of said rim, the traction-surfaces of said tire having grooves with short lateral branches forming pockets, substantially as set forth.

3. The combination, in a vehicle-wheel, of a central portion, and a tire secured to the periphery thereof, said tire having grooves in its traction-surfaces, and said grooves having branches forming cavities or pockets arranged in staggered relation to each other, substantially as set forth.

699,995. ENGINE. GEORGE E. WHITNEY, Boston, Mass., assignor to Whitney Motor Wagon Company, Albany, N. Y., a Corporation of Maine. Filed Jan. 23, 1903. Serial No. 92,699. (No model.)

Claim.—1. An engine containing a piston-rod, a connecting-rod, a crank-pin joining the two, a guide and a guide-wheel mounted on said crank-pin.

2. An engine containing a piston-rod, a connecting-rod, a guide-wheel connected with and moved by said piston-rod, and guides arranged at opposite sides of said guide-wheel.

3. An engine containing a piston-rod, a connecting-rod, a plurality of guide-wheels having coincident axes arranged at opposite sides the axis of said connecting-rod and connected therewith and movable thereby and guides for said wheels.

4. An engine containing a piston-rod, its connecting-rod, a cylindrical guide-wheel and a guide therefor, said guide and guide-wheel together presenting perpendicular side guiding means to receive the side thrust of said wheel.

5. In an engine a connecting-rod having a forked end, a wrist-pin provided with conical portions firmly held therein, a cross-head in which said wrist-pin turns, and a plurality of guide-wheels mounted on said wrist-pin and guides therefor.

6. In an engine having a wheel cross-head, a pair of wheels, a connecting-rod and a cross-head arranged between said wheels, a wrist-pin extended through said cross-head, connecting-rod and wheels, with means outside said wheels and acting upon the parts between said wheels but not by means thereof, to move said wrist-pin axially.

699,996. GRADNER. EPHRAIM WILLIAMS, Foster, Mo. Filed Nov. 19, 1901. Serial No. 88,912. (No model.)

Claim.—1. In a grader or the like, the combination with a main beam, and a scraping-blade adjustable with relation thereto, one of said members being provided with a tie-rod support and the other thereof being provided with a plurality of tie-rod supports, of a tie-rod adapted to simultaneously engage supports upon the said beam and blade and thereby

by adjustably space the said members apart, two of the said supports upon the member provided with the plurality thereof being so spaced that they are adapted to be simultaneously engaged by said tie-rod and thereby support the same; substantially as described.

2. In a grader or the like, the combination with a main beam, and a scraping-blade adjustable with relation thereto, each of said members being provided with a plurality of tie-rod supports, of a plurality of tie-rods of different lengths, each of which rods is adapted to simultaneously engage supports upon the said beam and blade and thereby adjustably space said members apart, two of the said supports upon one of said members being so spaced that they are adapted to be simultaneously engaged by one of said tie-rods, and two of the said supports upon the other of said members being so spaced that they are adapted to be simultaneously engaged by the other of said tie-rods, whereby said respective rods can be carried by said respective members; substantially as described.

3. In a grader or the like, the combination with a main beam, and a scraping-blade adjustable with relation thereto, each of said members being provided with a plurality of tie-rod supports, of a plurality of tie-rods of different lengths, each of which rods is adapted to simultaneously engage supports upon the said beam and blade and thereby adjustably space said members apart, each of said members having supports so spaced that each supports upon a respective member are adapted to be simultaneously engaged by one of said rods, whereby said rod can be supported upon either of said members, and one of said members having a support adapted to be engaged by the other of said tie-rods when one of said rods is supported upon said member; substantially as described.

4. In a grader or the like, the combination with a main beam, and a scraping-blade adjustable with relation thereto, each of said members being provided with a plurality of tie-rod supports, of a plurality of tie-rods of different lengths, each of which rods is adapted to simultaneously engage supports upon the said beam and blade and thereby adjustably space said members apart, supports upon one of said members being so spaced that they are adapted to be simultaneously engaged by one of said tie-rods, and three supports upon the other of said members being so spaced that when said tie-rod engages the central of said supports it can simultaneously engage either of the other of said two supports; substantially as described.

5. In a grader or the like, a main beam, a scraping-blade adjustably supported with relation thereto, and a flexible draft connection having one end attached to said beam and its other end attached to said blade and adapted to be engaged at either of a plurality of points by a draft appliance; substantially as described.

6. In a device of the character described, a guiding-rod comprising a plate having one portion formed into a blade and another portion formed into a handle; substantially as described.

699,997. MIA. JAMES W. WOODMAN, Danbury, N. Y. Filed Nov. 30, 1901. Serial No. 84,546. (No model.)

Claim.—1. In a device of the class described coupling-standards, segmental ribs having grooved edges between the standards, a cement filling in said grooves, and tightening-bands connecting the standards.

2. In a device of the class described, coupling-standards, tightening-bands connecting the standards, an opening between two adjacent standards, a door for closing said opening having staples through which a tightening-band passes whereby the door may be swung outwardly and then said inwardly to a position in which it bears upon one of the edges of the opening to maintain it in open position.

3. In a device of the class described coupling-standards, courses of segmental filling-pieces between the standards tightening-bands between the standards located over the joints between the courses of filling-pieces and means for tightening the bands.

699,998. MIA. JAMES W. WOODMAN, Danbury, N. Y. Filed Jan. 7, 1902. Serial No. 83,785. (No model.)

Claim.—1. In a silo composed of a frame formed of upright beams, spaced apart and held by rods, said frame being embedded in concrete, having air-spaces therein, in combination with a series of elastic door-openings doors in said openings plus for operating said doors located in the holes in the ways B, said openings extending from top to bottom all substantially as heretofore shown and described.

2. In a silo composed of a frame formed of upright beams, spaced apart and held by rods said frame being embedded in concrete, having air-spaces therein, in combination with a series of elastic door-openings extending from top to bottom, doors in said openings plus located in the holes in the ways B, and grooved strips or ways B, on the inner and outer sides of the silo, and each side of a continuous narrow opening extending from top to bottom all substantially as heretofore described.

3. A silo composed of a frame formed of upright beams spaced apart and held by rods, said frame being embedded in concrete having air-spaces therein.

699,999. MILLER-BRACE. JOHN R. WORTH and CHARLES R. FAIRWEATHER, Danbury, Pa. assignors to J. & W. Worth and W. P. Worth, Danbury, Pa. Filed Nov. 30, 1901. Serial No. 84,588. (No model.)

Claim.—1. As a new article of manufacture, a boiler-plate made of a single sheet of metal bent so as to form a body portion of double thickness, a head portion of double thickness connected to the body portion by a single thickness of metal and having feet of single thickness, substantially as described.

2. As a new article of manufacture, a boiler-plate made of a single sheet of metal bent so as to form an inclined body portion of double thickness, a head portion, said head portion having wings bent upon the head portion, and having feet spread apart and forming a channel, substantially as described.

3. As a new article of manufacture, a boiler-plate made of a single sheet of metal having an inclined body portion of double thickness, a head portion of double thickness and feet extending from each side of the base of the inclined portion, the base of the inclined portion being spread

apart forming a V-shaped channel between the feet, substantially as described.

4. A blank for a boiler-plate consisting of a single sheet of metal having a body portion a, a head portion b, wings c projecting from each side of the head portion, and portions d projecting at an angle from the opposite end of the body portion, substantially as described.

700,000. WORK-HOLDING DEVICE FOR BORING-MACHINES. McLENNAN YOUNG, Frederick, Md., assignor to Palmetto Fire Company, a Corporation of Maryland. Filed Nov. 30, 1901. Serial No. 88,773. (No model.)

Claim.—1. In combination with a borer, a carriage movable to and from the same, a work-holding table, a frame containing said table and extending in front of the same, a pivotal connection between said frame and carriage, and means for adjusting said pivotal connection along the frame from a point in rear of the table to a point in front of the same.

2. In combination with a borer, a carriage movable to and from the same, a work-holding table, a frame containing the same, and a pivotal connection between the frame and carriage adapted to be located in advance of the plane of the table.

3. In combination with a borer, a block-holding table mounted on an axle located with reference to the table to permit the latter to be swung around and present the edge of the block to the action of the borer.

4. In combination with a horizontal borer, a carriage movable to and from the same, a frame pivoted to said carriage on a vertical axis, a work-holding table contained by said frame in rear of its axis and movable on a horizontal transverse axis.

5. In combination with a borer, a carriage movable to and from the same and formed with a series of vertical holes, a pivot-pin adapted to be removably seated in said holes, a frame provided with a series of holes

adapted to receive the upper end of the pin, and a work-holding table mounted by said frame.

6. In combination with a horizontal borer, a carriage movable to and from the same, a frame 15 mounted on the carriage below the level of the borer on a vertical axis, a superstructure fixed to the frame at or near the level of the borer, and a work-holding table mounted on the superstructure on a transverse horizontal axis, in such position that the face of the table will be in rear of the axis of the frame 15; whereby the table may be swung around on the axis of the frame 15 to present the edge of the block to the borer, and may be swung vertically on its horizontal transverse axis relative to the superstructure without interference with the frame 15.

7. In combination with a horizontal borer, a frame, a work-holding table mounted on the frame on a horizontal transverse axis, means for adjusting the axis of the table to and from the face of the same, a counterweight connected with the table, and means for adjusting the counterweight with relation to the table to and from its axis.

8. In combination with a borer, a frame, a work-holding table, arms extending rearwardly from the same and pivoted to the frame on a transverse axis, means for adjusting the axial connection of the arms, a rod 23 pivoted to one of the arms on a horizontal transverse axis, means for adjusting the pivoted rod in its path of movement on its axis, and a weight carried by the rod.

9. In combination with a main frame, guides or tracks thereon, a vertical standard at one end of the frame, a horizontal borer mounted in the standard and overhanging the tracks at one end, a carriage provided with front wheels adapted to travel on the tracks and movable to and from the borer, a table on the carriage arranged to present the block to the borer when the carriage is moved up to the same, and horizontal plates fixed to the main frame and extending above the tracks below the borer, said plates being so positioned with relation to the tracks as to closely overlie the front wheels of the carriage when the latter is moved up to present the block to the borer; whereby the plates serve the three-fold functions of supports for the blank blocks to be bored; shields to prevent the drillings from gaining access to the tracks and wheels of the carriage, and stops to prevent the carriage from accidentally lifting from the track.

10. In a machine of the type described the combination with a drill, of means for presenting a block at an inclination to the same, and a gage device fixed to the drill and having its end beveled to permit the drill to enter the inclined block.

11. In a machine of the type described the combination with a drill, of means for presenting the block to the same, and a gage device on the drill having a conical end.

12. In a machine of the type described, the combination with a drill, of means for presenting the block to be bored to the same, and a gage device on the drill formed with a conical end, and adjustable along the drill.

700,001. EASY FURNITURE. WILLIAM F. ABELL, Derby, England. Filed Feb. 6, 1901. Serial No. 42,264. (No model.)

Claim.—A pen or enclosure device of the class specified consisting of four separate parts, panels or sections, two of which are hinged together and are shorter than the other two and are of the same length, the other two being also hinged together and hinged to the first two and being also of the same length, each of said parts or sections being composed of separate parts or strips connected with the corner-posts so as to turn thereon, four of said posts being employed, substantially as shown and described.

700,002. PICK-UP TONGS FOR LIVE WIRES. ANDREW ANDERSON, Decatur, Ill., assignor to Carter-Danahy Company, Keokuk, Iowa, a Corporation of Iowa. Filed Nov. 20, 1901. Serial No. 34,123. (No model.)

Claim.—1. In a tong for picking up and handling live wire, the combination of a pair of straight parallel bars conjoined at their ends and separated except at their ends, and a straight bar shorter than the distance between the connected ends of the parallel bars, the single bar being pivoted between the parallel bars to occupy the space between the same, and the single bar and the compound bar comprising the handles and jaws of the tong.

2. In a tong for handling wire, the combination of a pair of parallel bars conjoined at their ends and separated between their ends, and

other bar pivoted between the parallel bars with its jaw part swingable between the jaw part of the parallel bars, and a flexible line connected with the handle end of the single bar and extended through the handle end of the compound bar.

700,003. CLOTHES-LINE REEL AND STRETCHER. CARL G. ANDERSON, Des Moines, Iowa, assignor to E. Hartman, Des Moines, Iowa. Filed Mar. 5, 1901. Serial No. 42,692. (No model.)

Claim.—An improved clothes-line reel and stretcher, comprising in combination a support provided with slots 11, having the slots 14 therein, and having a curved back 12, a post pivoted to one side of said support, semicircular rollers 15 pivoted to the supports adjacent to the slots 14, an axle 18, flanges 19 thereon, a ratchet 20 thereon, and a crank 22 thereon, said axle being designed to enter the slots 14, and a back 25, a box 26 open at one side, and hinged to the back, and means for securing the free end of the box to the upper end of the back, whereby the reel and stretcher may be inclined, substantially as, and for the purposes stated.

700,004. SUTTERING. EDWIN J. ANDERSON, Erie, Pa. Filed Nov. 20, 1901. Serial No. 34,573. (No model.)

Claim.—1. The combination in a shaft-governor of a carrier, an eccentric pivotally mounted thereon and adapted to be shifted through a suitable range, a centrifugal weight, a spring upon which said weight is mounted and means whereby said weight and eccentric are so connected that their movements will be in opposite directions and of approximately equal gravity amount, thereby balancing the weight of the eccentric and also so that the centrifugal force exerted by the weight shall not be transmitted through the pivot of the governor.

2. The combination in a shaft-governor of a carrier, an eccentric pivotedly mounted thereon and adapted to be shifted through a suitable range, a centrifugally-acting weight, a spring upon which said weight is mounted, and a longitudinally-adjustable link connecting said eccentric and weight in such a manner that their movements shall be in opposite directions.

700,005. COOLING APPLIANCE. THOMAS S. ARMSTRONG, North Plainfield, N. J. Filed Nov. 12, 1901. Serial No. 52,504. (No model.)

Claim.—1. In a cooling appliance of the character described, the combination with the vessel for holding the cooling agent, said vessel being open at the top and having a drawing-off tube at the bottom whose inner end projects inward toward the center of the vessel and having a collar projected up from the bottom thereof; of a retainer or beverage-holder, said holder having pendant supporting-brackets at the bottom and having its lower end of a size to fit within the upper edge of the collar on the bottom of the vessel, the brackets projected radially inward from the upper end of the vessel adapted to engage the upper end of the said container or holder, one of said brackets being detachably held, the container or holder having an opening at the lower end, whereby it can be slipped onto the inner end of the drawing-off tube, and the clamping-nuts for securing the tube and the container all being arranged substantially as shown and for the purposes described.

2. In a cooling appliance of the character described, the combination with the vessel for holding the cooling agent, said vessel having a drawing-off tube and having a drawing-off tube whose inner end projects toward the center of the vessel, said projecting end being threaded, said vessel having an annular collar projected upward from its bottom, and a series of brackets projected radially inward from the upper end of the vessel, one of said brackets being disposed over the drawing-off tube and detachably held within the vessel; of the container or holder, said holder having pendant brackets at the lower end and having the said end of a diameter to fit between the upper edge of the collar at the bottom of the vessel, the lower end of the said holder being open, whereby it can be readily fitted over the projecting end of the drawing-off tube, clamping-nuts engaging the said tube for holding the container or holder in a fluid-tight engagement with the tube, all being arranged substantially as shown, whereby by releasing the nuts from the drawing-off tube, and removing the detachable bracket, the container or holder can be tilted and slipped from engagement with the inner end of the drawing-off tube, substantially as shown and for the purposes described.

3. The heretofore-described improvement in cooling appliances, comprising a vessel adapted to hold the cooling agent, said vessel having

an annular collar projecting vertically upward from the bottom and having a plurality of brackets projected radially inward, said brackets being fixedly connected to the interior of the vessel; another bracket of like structure projected radially in line with the other brackets, said bracket being detachably connected with the inner side of the vessel, an externally-threaded drawing-off tube, one end of which projects through the vessel and has an internally-threaded outer end, the inner end of said tube projecting inward to a point over the collar on the bottom of the vessel, said end being threaded, the container having pendant bracket members adapted to straddle the collar on the bottom of the vessel, said vessel-bottom being arranged to fit within the upper end of the collar, the upper end of said vessel projecting above the brackets, said brackets and the container being relatively of such proportions that the brackets will form lateral braces for the said container, the container having an elongated opening at the lower end, whereby it can be fitted over the inner end of the externally-threaded drawing-off tube, and the nuts and washers for effecting a tight adjustment of the container, the vessel, and the drawing-off tube, all being arranged substantially as shown and for the purposes described.

700,006. ARM-REST FOR BOOKS. JAMES BARKER, Detroit, Mich. Filed Aug. 14, 1901. Serial No. 74,392. (No model.)

Claim.—1. The combination with a book, of a member secured to the end thereof, a support detachably connected to said member, and an arm-rest mounted upon the support for longitudinal movement along the edge of the book.

2. The combination with a book, of a transverse member secured to the book at one end thereof, a support detachably connected to said member, a longitudinal guide-bar upon the support, an arm-rest, and connections between said guide-bar and arm-rest permitting movement of the latter along the lower edge of the book.

3. In an arm-rest for books, the combination of a support, a longitudinal guide-bar thereon, a sliding block movable on the guide-bar, a transverse guide-bar on the sliding block, the arm-rest block sliding thereon, and the multiple-hinged arm-rest on said block.

4. In an arm-rest for books, the combination of a support, a longitudinal guide-bar thereon, a sliding block movable on the guide-bar, a transverse guide-bar on the sliding block, the arm-rest block sliding on the transverse guide-bar and the slidingly-hinged arm-rest on said block.

5. In an arm-rest for books, a support for the hinged arm-rest comprising a base adapted to engage the book-cover, a transverse bar at the end of the book, and a hook adapted to engage the bar.

6. In an arm-rest for books, the combination of a base adapted to engage beneath the book-cover, a transverse bar at the end of the book extending across between the covers, an upright hook engaging the bar, a standard beside said book, and an arm-rest supported upon the standard.

700,007. ROTARY ENGINE. BLAINE W. BARTON, Windsor, N. Y. Filed Sept. 4, 1901. Serial No. 74,394. (No model.)

Claim.—1. The combination with the casing having an annular steam-chamber, having a single exhaust, a rotary piston consisting of two separate sections, each having radial abutments and steam-pockets, these on one section being disposed intermediate those of the other section, and means for clamping the two sections to form a single rotary piston; of a steam-chest forming an attached part of the casing, a governor-regulated feed-pipe thereto, said chest having two independent ports that discharge into the piston-chamber, one for each piston-section, a single cut-off slide for controlling the said feed-ports, gearing connecting the said slide with the engine drive-shaft, and gearing including means for varying the movement of the cut-off slide, for the purposes specified.

2. In a rotary engine, as described, the combination with the casing having a single exhaust, and a steam-chest forming an attached part of the casing, and having two separate ports discharging into the piston-chamber, and the rotary concentrically-operating piston, said piston having two independent sets of abutments and steam-pockets alternately arranged relatively to each other; of a cut-off slide for controlling the steam-ports to the piston-chamber, said slide consisting of an angle-plate

having one member engaging and guided by the side wall of the casing, and its other member slidable over the steam-ports, and mechanism connected with and automatically operated by the drive-shaft for shifting said cut-off to alternately open and close the steam-ports, said mechanism including means for varying the throw of said cut-off slide, for the purpose specified.

2. In a rotary engine of the character described, the combination with the casing having a single exhaust, an exhaust-pipe therefor, and the rotary piston formed of sections each having independently-operating steam-ports and steam-pockets; of the steam-chest mounted on the casing, a valved drip-pipe connected with the casing and the exhaust exhaust-pipe, said chest having two ports discharging into the piston-chamber, a feed for the steam-chest having governor device, operated from the drive-shaft, a cut-off slide operating within the said chest for controlling the steam-ports, and means energized from the drive-shaft for shifting the cut-off, said means including hand act device for regulating the speed of said cut-off movement, as set forth.

700,008. PIPE-TOUCH. CHARLES F. BAKER, McCormickville, Ohio, assignor of one-half to George H. Bahr, McCormickville, Ohio. Filed Apr. 26, 1901. Serial No. 66,711. (No model.)

Claim.—The wrench herein described, consisting of the integral jaw and handle-bar having a single slot, the cooperating short jaw and its handle-lever separately formed and pivoted in said slot, and the thin link-plates extending through the said slot and connecting the short jaw and its handle-lever, substantially as modified.

700,009. WHEEL. JOHN BARR, Los Gatos, Cal. Filed Feb. 17, 1901. Serial No. 64,691. (No model.)

Claim.—1. In a wheel, a rotatable shell or body having an upwardly-extending bracket and a regulating-arc engaging therewith and supported thereby, and a rotatable valve having at its upper extremity and above the upper end of the shell or body an elliptically-formed head against which the end of the screw is adapted to impinge, substantially as and for the purpose set forth.

2. In a wheel, a rotatable shell or body having an outlet with side walls increasing in width in a direction near their center, said shell or body having a bracket extending out from the same, and a rotatable valve

having an elliptically-formed head at its upper end and above the shell or body, and a regulating-arc supported by the bracket and adapted to impinge against the elliptically-formed head, substantially as and for the purpose specified.

700,010. CIGARETTE-MACHINE. FRANK B. BRATTON, South Norwalk, N. Y. Filed Jan. 14, 1901. Serial No. 66,722. (No model.)

Claim.—1. In a cigarette-machine, the combination with a pair of conical members hinged together, and one provided with a laterally-projecting tablet; of a guide-plate supported a short distance from the surface of the tablet and having its inner edge portion inclined toward the line of junction of said cylindrical portion and tablet; a ribbon-guide on the other member; and a ribbon inserted between said members, and having one end projecting exteriorly through said ribbon-guide, and the other end exteriorly between said tablet and guide-plate, substantially as described.

2. In a cigarette-machine, the combination with a pair of conical members hinged together, and one provided with a laterally-projecting tablet; of a guide-plate supported a short distance from the surface of the tablet and having along its inner edge a series of teeth inclined toward the line of junction of said cylindrical portion and tablet; a ribbon-guide on the other member; and a ribbon inserted between said members, and having one end projecting exteriorly through said ribbon-guide and the other end exteriorly between said tablet and guide-plate, substantially as described.

700,011. BOAT OR VESSEL. JULIUS F. BUCK, Hamburg, Germany. Filed Aug. 27, 1901. Serial No. 73,496. (No model.)

Claim.—In a ship, boat, or other vessel, the combination, of a hinged mast, a toothed segment rigidly secured to said mast below the hinge, a shaft, a second toothed segment, secured on said shaft and meshing with the segment secured to the mast, a third toothed segment, secured to said shaft, a lever carrying a weight, a fourth toothed segment, secured to said lever, substantially as, and for the purpose, set forth.

700,012. PROTECTIVE TUNNELING-HEAD FOR SHIP HATCHES. JOHN BRADSHAW, New York, N. Y. Filed Feb. 12, 1901. Serial No. 67,781. (No model.)

Claim.—1. The combination with an inwardly-projecting arm secured to the upper end of the article to be protected and provided with

a nut at its free inner end, of a screw-threaded rod screwing into the nut of the cone and provided with a ball at its upper end, and a conical head having a socket on its inner face at the apex to receive the ball of the rod, said head being of a diameter considerably greater than that of the article and adapted to be seated on the upper edge of cone, as set forth.

2. The combination with a hatch having a packing around the upper edge of its outer surface, of an inwardly-projecting arm having one end secured to the hatch and provided with a nut at its free inner end, a screw-threaded rod screwing in the nut of the arm and provided with a ball at its upper end, and a conical head having a socket on its inner face at the apex and in which the ball of the rod fits, said head being of a diameter considerably greater than that of the hatch and adapted to be seated on the packing-ring at the upper edge of the hatch, as set forth.

700,018. SHIRT-BAND STIFFENER. ARTHUR B. BOONER, Paris, France, assignor to Jules Louis Vincent, Paris, France. Filed Feb. 14, 1900. Serial No. 94,162. (No model.)

Claim.—1. A stiffener for a shirt-band consisting of two sections of thin, resilient material hinged together at their ends, said stiffener being provided, adjacent to the hinge, with a stud.

2. A stiffener for a shirt-band consisting of two similar sections of thin, resilient material hinged together at their overlapping ends and one of said sections having a stud attached to it below and adjacent to the hinge.

700,014. ADJUSTABLE BUSHING. GERHARD P. BOCK, Prout Royal, Va. Filed Aug. 13, 1901. Serial No. 71,888. (No model.)

Claim.—1. An adjustable bushing or packing consisting of a strip of thin flat metal wound in the form of a roll and solder connecting the edges of said strip, substantially as described.

2. An adjustable bushing or packing consisting of a strip of thin flat flexible metal wound in the form of a roll and the edges of said strip soldered together, whereby a bushing or packing is formed with smooth solid ends, substantially as described.

3. The combination with a bearing-cap, of an adjustable bushing consisting of a thin flat flexible strip of metal wound upon said cap and solder connecting the edges of said strip, whereby a bushing is formed with smooth solid ends, substantially as described.

700,015. CASING POINT OR STRAINER. ANDREW E. CARLSON, Memphis, Tex. Filed Apr. 9, 1901. Serial No. 88,040. (No model.)

Claim.—1. A well-strainer comprising a pipe having a bottom inlet, a rigid frame depending below the pipe, trussed rods arranged longitudinally of the pipe and in a series around the same and at their upper ends secured to the pipe and at their lower ends secured to said frame, said rods between their ends arranged a distance from the outer surface of the pipe, and a strainer-covering arranged around the series of rods, substantially as described.

2. A well-strainer comprising a pipe having a bottom inlet and radial supports projecting beyond the outer wall of the pipe, rods arranged longitudinally of the pipe and in a series around the same and drawn in-

wardly and secured at their end portions, said rods between their end in-ward portions being held away from the outer surface of the pipe by said supports, a strainer-covering around said series of rods and tapering oppositely at the end portions, substantially as described.

3. In combination, a pipe having an open lower end, the legs secured to and projecting below the pipe end, the strainer-plate secured to the lower ends of said legs, the ring on the legs above the strainer-plate, rods arranged longitudinally of the pipe and in a series around the same, said rods at their upper ends secured to the pipe and at their lower ends secured to said ring, the radial studs projecting from the pipe and engaging said rods between their ends and holding the same a distance from the surface of the pipe and forming the series of rods tapering inwardly and upwardly at the upper end, a strainer-covering around the series of rods, and exterior guard-rings around said covering, substantially as described.

4. A casing point or strainer comprising a well tube or casing, a framework secured thereto and arranged longitudinally thereof and extending below said tube and having a longitudinally-tapered end, a strainer-covering around said framework and conforming to the tapered end thereof, and a guard-ring slipped over and wedged on the exterior of said covering and located at the large end of said tapered portion, substantially as described.

5. A casing point or strainer comprising a well tube or casing, rods rigid therewith and projecting longitudinally beyond the end thereof, an end plate carried by said rods a distance beyond the end of the casing, a framework extending longitudinally of the casing and at the upper end secured thereto and at the lower end secured to said rods, and a strainer covering around and the length of said framework, substantially as described.

6. A casing point or strainer comprising a well-tube having an end inlet, a frame rigid with and projecting below said end of the tube and having a perforated bottom floor a distance below said tube end, a framework extending longitudinally of said tube and at its upper portion tapered inwardly and upwardly and secured to said tube and below its upper end held away from said tube and extending below the tube and at its lower portion secured to the lower portion of said frame, and a strainer covering around and the length of said framework and forming a water-space around and below the tube, substantially as described.

7. In combination, the pipe or casing having a lower inlet end, and a strainer movable into and out of the well with said pipe and comprising a framework surrounding said pipe and arranged longitudinally thereof from a point above said inlet end to a point below the same, said framework between its ends held away from the exterior of the pipe to form a water-circulating space around the same, and having its upper end tapered upwardly and inwardly to the pipe and secured thereto, means rigid with and projecting below the pipe, the lower end of said framework tapered inwardly and downwardly and secured to said means below said inlet end of the pipe, a strainer-covering around said framework, and exterior guards around said strainer-covering and projecting beyond the same to prevent injury thereto as the pipe is inserted in or removed from the well, substantially as described.

8. In combination, a pipe having an inlet, rods arranged longitudinally thereof and in a series around the same and at their upper ends secured to the pipe a distance above said inlet, and at their lower ends projecting below the inlet, means rigid with said pipe and to which the lower ends of said rods are secured, the lower ends of said rods being threaded

and provided with nuts screwing thereon for tightening the rods and securing the same at their lower ends, and a strainer-covering around said series of rods and forming a water-circulating chamber around said pipe, substantially as described.

9. In combination, a pipe having an inlet, an open framework arranged longitudinally of said pipe from a point above said inlet to a point below the same, said frame at its upper end secured to the pipe and at its lower end provided with means securing it to the pipe, opening devices arranged between the pipe and intermediate portions of the framework and holding said framework, between its ends, away from the pipe, whereby the ends of the framework are tapered inwardly, in opposite directions, and a strainer-covering around said framework and forming an open water-space within the framework around the pipe, substantially as described.

10. In combination, a pipe having a lower inlet end, legs rigid with and depending below said end, a perforated bottom plate secured to said legs, an open framework arranged longitudinally of said pipe and secured thereto and between its ends trained therefrom and extending down to said plate and confined to said legs, and a strainer-covering around and throughout the length of said framework, substantially as described.

11. In combination, a pipe having a lower inlet, an open framework including, secured to and arranged longitudinally of said pipe from a point above to a point below said inlet, said framework at one end fixedly secured and at the opposite end provided with longitudinally-screw-threaded portions and nuts thereon securing the frame and drawing the same longitudinally taut, an abutment for said nuts, and a strainer-covering around said framework and forming a water-space within the same, substantially as described.

12. In combination, the pipe having a bottom inlet, an open framework arranged around the pipe and extending longitudinally thereof, the upper end of said framework drawn inwardly on an upward taper to the exterior surface of the pipe and there secured to said pipe, means securing the lower end of the framework rigid with the pipe, the lower end of the framework drawn inwardly on a downward taper, and a strainer-covering secured around said framework, substantially as described.

13. In combination, a pipe having a bottom inlet, a series of rods arranged around and extending longitudinally of said pipe and at their upper ends secured to the pipe, a plate through which the lower ends of said rods pass, means confining said plate to the pipe, the lower ends of said rods longitudinally threaded and provided with tightening and securing nuts, and a strainer-covering around said rods, substantially as described.

14. In a well-strainer, in combination, an uptake pipe or casing having a lower inlet end, and an open framework secured to and carried by said casing and arranged longitudinally of said casing and projecting a distance below the inlet end thereof, said framework comprising a series of rods arranged longitudinally of and in a series around the casing, means confining said rods at their ends, and intermediate spacing or supporting devices arranged within the series of rods and engaging the same, said series of rods having a diameter greater than the exterior diameter of the casing, and a strainer-covering around the exterior of the series of rods, substantially as described.

15. In combination, in a well-strainer, an uptake pipe or casing having a lower inlet end, and an open framework secured to said casing above its inlet end and extending longitudinally thereof to a point below the same and comprising a bottom head or plate, a multiplicity of rods confined at their ends and arranged longitudinally of said pipe and in a series around the same and at their lower ends confined to said bottom head, and intermediate spacing or securing devices arranged at intervals within the series of rods and formed to fit the individual rods, and a strainer-covering wrapped around the exterior of the series of rods, substantially as described.

700,016. MECHANISM FOR SECURING LARS TO CARRIER-CHAINS. CARL S. CARLSON and ARTHUR TUNALL, Duluth, Pa. Filed Dec. 26, 1901. Serial No. 87,967. (No model.)

Claim.—1. The combination in a mechanism for securing lars to a carrier-chain, of a curved loop or stirrup, and a curved cross-bar secured to the rear end thereof, substantially as set forth.

2. The combination with a carrier-chain, of legs, loops or stirrups extending from the fronts of said legs through links of the carrier-chain,

and curved cross-bars extending upward from the backs of said legs through links of said chain substantially as set forth.

700,017. CORE-CULTIVATOR. CHARLES H. GARDNER, Chicago, Ill. Filed Feb. 10, 1902. Serial No. 92,851. (No model.)

Claim.—1. In a cultivator an arched axle, a frame rigid with the axle, a movable arched frame, means for adjusting it, beams having their ends connected to the arched frame, crank-levers mounted in the bearings, connections from the cranked levers to the beams, cam-tripping blocks on the wheels and means for projecting the crank-levers into contact with the tripping-blocks.

2. In a cultivator, an arched axle, a frame rigid thereon, a movable frame having depending ends, segmental racks carried by the rigid frame, levers pivoted on the racks, connections from the levers to the beams, crank-levers mounted in bearings on the axle, connections from the beams to the crank-levers, springs coacting with the crank-levers, tripping-blocks on the wheels and means for projecting the crank-levers into the path of travel of the tripping-blocks.

3. In a cultivator, an arched axle, ground-wheels thereon, a frame rigid with the axle, a movable frame, a lever for adjusting the movable frame, pivot-beams, connected to the movable frame, crank-levers suitably mounted, tripping-blocks on the wheels and means whereby the crank-levers are moved into engagement with the tripping-blocks, as and for the purpose described.

700,018. BAKE-OVEN. WILLIAM CLARK, Cincinnati, Ohio. Filed Nov. 26, 1901. Serial No. 90,502. (No model.)

Claim.—1. An oven having a baking-chamber, a fire-box at one side and below the baking-chamber, a partition below the baking-chamber and provided with a passage one end of which is extended to the outside of the oven and provided with a door, two flues at opposite sides of said partition, respectively, and extended from the fire-box toward the opposite side of the oven, other flues outside of and in the same vertical plane with and adapted for communication with the first-named flues, means for circulating the products of combustion from said flues above the baking-chamber, a shaft extended down through the baking-chamber and having its lower end in the passage below said chamber, a step-bearing for said shaft in said passage, driving means for said shaft and a plate on said shaft within the baking-chamber to support articles to be baked, substantially as set forth.

2. An oven having a baking-chamber, a fire-box at one side and below the baking-chamber, a partition below the baking-chamber and provided with a passage one end of which is extended to the outside of the oven and provided with a door, two flues at opposite sides, respectively, of said partition and extended from the fire-box toward the opposite side of the oven, other flues outside of and in the same vertical plane with and adapted for communication with the first-named flues, upwardly-extended flues adapted for communication at their lower ends with the outside flues below the baking-chamber, two sets of flues in the

case plane above the baking-chamber, the outer line of each set having communication with one of said upwardly-extended lines and the inner line of each set being adapted for communication with a smoke-outlet, a shaft extended down through the baking-chamber with its lower end in the passage below said chamber, a step-bearing for said shaft in said passage, driving means for said shaft and a plane on said shaft within the baking-chamber to support articles to be baked, substantially as set forth.

3. An oven having a baking-chamber, means for heating the same, a vertical shaft in said chamber, arms extended radially from the shaft and provided with depressions, plaster in said depressions and a covering for said arms held thereon by said plaster, substantially as set forth.

4. An oven having a baking-chamber, means for heating the same, a vertical shaft extended in said chamber, arms extended radially from the shaft, parts extended intermediate the outer ends of said arms, each of said arms and intermediate parts having a longitudinal flange and depressions, plaster in said depressions and a covering formed in sections held on said arms and intermediate parts between said longitudinal flanges, substantially as set forth.

5. An oven having a baking-chamber, means for heating the same, a vertical shaft in said chamber, driving means for said shaft, a plane for supporting articles to be baked and formed of a framework and a covering supported thereon, a collar on the shaft below said plane, diagonal braces extended from said collar up to said framework, a central collar on the shaft, and brace-rods having oppositely-arranged threaded ends, each such brace-rod having one end engaged with said central collar and its opposite end engaged with one of said diagonal braces, substantially as set forth.

6. An oven having a baking-chamber, a fire-box, a partition below the baking-chamber and forming on its opposite sides flues having communication with said fire-box, said partition having a passage one end of which is extended to the outside of the oven-wall and provided with a door, a vertical shaft in the baking-chamber with its lower end extended in said passage-way, a plane on the shaft in the baking-chamber, and a step-bearing for said shaft in said passage, substantially as set forth.

7. An oven having a baking-chamber, means for heating the same, a vertical shaft extended in said chamber, a plane within the chamber and on said shaft, braces having their lower ends supported adjacent to the shaft and below said plane, said braces being extended upward with their upper portions inclined out from the shaft and arranged to support said plane and devices for drawing the inclined upper portions of the braces toward said shaft for raising said plane, substantially as set forth.

8. An oven having a baking-chamber, means for heating the same, a shaft extended in said chamber, arms extended radially from said shaft, a covering rested on said arms and forming a plane for supporting articles to be baked, means for driving said shaft and an annular part rested on said arms at the center of said plane and provided with a raised flange against which the covering of the device has engagement to hold said covering against displacement, said annular part being also provided with downwardly-extended portions having engagement between said arms to hold said annular part in position on the arms, substantially as set forth.

9. An oven having a baking-chamber, means for heating the same, a vertical shaft extended in said chamber, a plane within the chamber and on said shaft, braces having their lower ends supported adjacent to the shaft and below said plane and having their upper portions extended upward and inclined out from the shaft, a collar held on the shaft and brace-rods having their inner ends engaged with the collar and having at their outer ends adjustable connection with said inclined braces, substantially as set forth.

10. An oven having a baking-chamber, means for heating the same, a vertical shaft in the chamber, a plane on the shaft in the chamber, means for driving the shaft, the lower end of the shaft having a central recess and being provided with a flanged collar, an anchor-plate beneath the lower end of the shaft, a stirrup comprising upwardly-extended spaced arms produced on said anchor-plate, two correspondingly-grooved bearing-plates one above the other and provided with central openings aligned with the central recess in the lower end of the shaft, the lower bearing-plate being rested on the stirrup and the flanged collar of the shaft being rested on and secured to the upper bearing-plate, balls interposed between the bearing-plates and engaged in the grooves thereof, a stud having its upper end engaged in the central recess in the lower end of the shaft, said stud being passed down through the central openings in the bearing-plates, the stirrup having a central bearing at its upper part in which the lower end of said stud is engaged and a screw carried by the stirrup with its upper end engaged under the lower end of said stud and its lower end formed with a head at the under side of the upper part of the stirrup and between the two arms thereof, substantially as set forth.

Claim.—1. In a collection-recording mechanism, a recording device located at a central office, an electric circuit in which the recording device is located, a circuit-controller supported on a letter-box for opening and closing the electric circuit and means in the circuit for marking the box, substantially as specified.

2. In a collection-recording mechanism, a recording device located at a post-office, electric devices for causing movements of the recording device, an electric circuit in which the electric devices are placed, and a circuit-controller supported on a letter-box and operated by a movement of the letter-box door, substantially as specified.

3. In a collection-recording device, a recording mechanism, comprising printing-wheel, electric devices for causing movements of said printing-wheel, for printing on a record-strip, electric devices for controlling the feeding of said record-strip, an electric circuit in which said electric devices are located, and a circuit-controller supported on a letter-box and operated by a movement of the letter-box door, substantially as specified.

4. In a device for recording the collection of mail-matter, a recording mechanism adapted to be located at a central office and comprising printing-wheel, platens movable relatively to said printing-wheel, an electromagnet for causing the movements of said printing wheel to print the number of the box from which the collection is made, means for imparting motion to others of the printing-wheel, electric devices for moving the platens, electric devices for causing the feeding movement of a record-strip, an electric circuit in which said electric devices are arranged, and a circuit-controller located on a letter-box and operated by an opening movement of the letter-box door, substantially as specified.

5. In a collection-recording mechanism, a recording device, comprising printing-wheel for printing on a strip the number of a letter-box, printing-wheel for printing the time of the collection from said letter-box, said last-named printing-wheel being adapted for connection with a clock mechanism, an electric device for operating the first-named wheel, means for causing a step-by-step movement of a paper strip, platens for moving the paper against the printing-wheel, electric devices for controlling the movements of said platens, an electric circuit in which the electric devices are arranged, and a circuit-controller in the circuit and attached to the letter-box, the said circuit-controller being operated by a movement of the letter-box door, substantially as specified.

6. In an apparatus for recording the collection of mail-matter, a recording mechanism located at a post-office, said recording mechanism comprising printing-wheel, for printing on a record-strip movable along said wheel, platens movable under the printing-wheel, means for moving the printing-wheel to printing position, means for moving the platens toward the printing-wheel when in such printing position, means for feeding the strip after the printing, electric devices for controlling the movements of said printing-wheel, platens and paper strip, an electric circuit

in which said electric devices are arranged, and a circuit-closer in the circuit and arranged on a letter-box, the said circuit-closer being operated by a movement of the letter-box door, substantially as specified.

7. In a collection-recording mechanism, a recording apparatus, comprising printing-wheels, an electric circuit, electric devices in said circuit for causing movements of certain of the printing-wheels, a circuit-closer operated by a letter-box door for closing and opening said circuit, a record-strip-feeding device, comprising a sliding block, a gripping-dog pivoted to said block, a rod extended from said dog, a spring for moving the rod in one direction, a rotating shaft, a disk loosely mounted on said shaft and having a lag, electrically-controlled means for locking said disk to the shaft, causing said lag to engage with said rod and move it in one direction, and a platen also operated by said lag, substantially as specified.

8. In a collection-recording mechanism, a recording apparatus located at a post-office or the like, electric devices for operating the printing apparatus, an electric circuit in which said electric devices are located, and a circuit-closer comprising a casing attached to a letter-box, a disk mounted in said casing and having blocks of insulating material spaced apart, a contact-point engaging with the periphery of said disk, said contact-point being arranged in the electric circuit, a spring for rotating said disk, and means actuated by an opening movement of the letter-box door for winding said spring, substantially as specified.

9. A mail-collection-recording mechanism, comprising a recording device arranged at a central station, electrically-controlled means for causing movements of the recording apparatus, an electric circuit in which said electrically-controlled means are located, a circuit-closer, comprising a casing adapted to be secured to a letter-box, a disk mounted to rotate in said casing and having insulating-blocks spaced apart in its periphery, a contact-pin engaging with the periphery of said disk, a spring for causing a movement of said disk in one direction, a connection between said spring and the pin of the box-door hinge, whereby the spring will be wound upon opening the door, a governor for the spring, and a brake for the disk, substantially as specified.

10. In a mail-collection-recording mechanism, two printing-wheels for printing the number of a letter-box from which mail is collected, ratchet-wheels mounted on the shafts of said printing-wheels, escapements for engaging with said ratchet-wheels, a tappet adapted for engagement with either one of said escapements, an electromagnet for causing the movement of said tappet from one escapement to the other, an electromagnet for moving the said tappet out of engagement with the escapement, a spring for moving the tappet into engagement with said escapement, an electric circuit in which the said electromagnets are located, and a circuit-controller in the circuit, said circuit-controller being attached to a letter-box and operated by an opening movement of the letter-box door, substantially as specified.

11. In a recording mechanism, a recording device, an electric circuit in which the recording device is located, a circuit-closer arranged in a box having a door, a spring for operating said circuit-closer in circuit-closing direction, and connections between said spring and the box-door whereby the spring is wound by opening movement of the door, substantially as specified.

12. In a recording apparatus, printing-wheels, means for causing the movements of said printing-wheels, a platen movable under certain of said printing-wheels, an electromagnet for causing an operative movement of said platen, an electromagnet for controlling the circuit through the first-named electromagnet, an electric circuit, and a circuit-controller located on a letter-box and operated by a movement of the letter-box door, substantially as specified.

13. In a recording mechanism, a recording device, an electric circuit in which the recording device is located, a letter-box having a door, a circuit-closer in the box and operated by a movement of the door, a lock for the door, and devices arranged in the electric circuit for releasing said lock, substantially as specified.

14. In a recording mechanism, a recording device arranged at a central station, an electric circuit in which the recording device is placed, a letter-box, a circuit-closer in said letter-box, a swinging latch for locking the door of the box, an electromagnet for moving said latch in one direction, the said electromagnet being arranged in the said electric circuit, and a device in the circuit for closing the same and energizing said electromagnet, substantially as specified.

700,020. COMBINED GAS AND AIR FEEDING ATTACHMENT FOR GAS-STOVE. JAMES DENNIS, JR., East Providence, R. I. Filed Mar. 27, 1901. Serial No. 53,021. (No model.)

Claim.—In a device of the character described, a member having a passage therethrough, a transverse partition in the member having an axially-disposed aperture therein, a curved partition having an aperture in alignment with said aperture, means for directing the gas to be mixed axially through one of said apertures, the member having an enlarged

chamber intermediate of said partitions whose interior walls at the inlet of said chamber are of a concave form and which walls are tapering at the outlet of the chamber, the member also having the portion of the passage extending beyond said aperture in the second partition disposed at an angle to the axis of said partitions, and having a cavity in the wall of the passage located opposite to the ridge formed by the bend.

700,021. ENAMELING-FORK FOR BATH-TUBS. EDWARD DITTMER, Elwood City, Pa. Filed Jan. 31, 1901. Serial No. 48,672. (No model.)

Claim.—1. In bath-tub handling apparatus, a movable support carrying a tub-fork, mechanism for rotating the fork on its axis, and mechanism for tilting the tub to different angles relatively to the fork-axis; substantially as described.

2. In enameling apparatus, an overhead support, an enameling-fork carried thereby, mechanism for raising and lowering the fork, mechanism for rotating the fork, and mechanism for tilting the tub to an angle with the axis of the fork; substantially as described.

3. An enameling-fork having pivoted side supports for the tub mounted thereon, and end clamping devices for the tub arranged to engage said side supports; substantially as described.

4. In enameling apparatus, a crane-post mounted in stationary bearings and having a horizontally-swinging arm, an enameling-fork supported from said arm, mechanism for rotating the fork around its axis, and mechanism for tilting the tub into an angular position with respect to said axis; substantially as described.

700,022. LITHOTYPE-MATRIX. PHILIP T. DYER, Washington, D. C., assignor to Mergenthaler Lithotype Company, a Corporation of New York. Filed Mar. 7, 1902. Serial No. 97,102. (No model.)

Claim.—1. A lithotype-matrix consisting of a body portion and a distinct portion secured to the body and provided with distributing-teeth.

2. A lithotype-matrix consisting of a body portion and a relatively hard portion attached thereto and containing the distributing-teeth.

3. A lithotype-matrix consisting of a relatively hard member B, provided with distributing-teeth and a body portion cast upon and latched with the member B.

4. A foot-type-machine comprising a hard metal strengthening member, and a cast-metal body portion cast upon and around the hard member and interlocked therewith to hold it in place, substantially as described and shown.

5. For a foot-type-machine, a cast-metal matrix, having portions of harder metal applied to reinforce and strengthen the core thereof.

700,038. CARPENTER'S TOOL. JAMES T. BENT, Leontine, N. J., assignor of one-half to William H. Bunt, Leontine, N. J. Filed Sept. 4, 1901. Serial No. 74,038. (No model.)

Claim.—1. A carpenter's tool or square comprising a base-plate having a front straight edge and composed of top and bottom parts, one of which is wider at the straight edge than the other, one end of said base-plate being also formed at a right angle to the straight edge thereof, and the other end at an angle of forty-five degrees to the said straight edge, and a plate set into the front straight edge of the base-plate longitudinally and centrally thereof and provided with two arms, which taper outwardly, the outer edge of one of said arms forming a right angle to the straight edge of the base-plate and the outer edge of the other arm forming an angle of forty-five degrees to the said straight edge of the base-plate, said plate being also cut out opposite the central portion of the base-plate as to form said arms and an angle of ninety degrees at the intersection of the adjacent edges of said arms adjacent to the middle of the base-plate, substantially as shown and described.

2. A carpenter's tool or square comprising a base-plate having a front straight edge and composed of top and bottom parts, one of which is wider at the straight edge than the other, one end of said base-plate being also formed at a right angle to the straight edge thereof, and the other end at an angle of forty-five degrees to the straight edge, and a plate set into the front straight edge of the base-plate longitudinally and centrally thereof and provided with two arms, which taper outwardly, the outer edge of one of said arms forming a right angle to the straight edge of the base-plate and the outer edge of the other arm forming an angle of forty-five degrees to the said straight edge of the base-plate, said plate being also cut out opposite the central portion of the base-plate as to form said arms and an angle of ninety degrees at the intersection of the adjacent edges of said arms adjacent to the middle of the base-plate, the arm, the outer edge of which forms an angle of ninety degrees to the straight edge of the base-plate being also provided with a plurality of rows of scale-holes and said arm being also provided centrally of the base thereof with a hole in line with the inner inclined edge of the other arm, substantially as shown and described.

3. A carpenter's tool or square comprising a base-plate having a front straight edge and composed of top and bottom parts, one of which is wider at the straight edge than the other, one end of said base-plate being also formed at a right angle to the straight edge thereof, and the other end at an angle of forty-five degrees to the straight edge, and a plate set into the front straight edge of the base-plate longitudinally and centrally thereof and provided with two arms which taper out-

wardly, the outer edge of one of said arms forming a right angle to the straight edge of the base-plate and the outer edge of the other arm forming an angle of forty-five degrees to the said straight edge of the base-plate, said plate being also cut out opposite the central portion of the base-plate as to form said arms and an angle of ninety degrees at the intersection of the adjacent edges of said arms adjacent to the middle of the base-plate, the arm, the outer edge of which forms an angle of ninety degrees to the straight edge of the base-plate being also provided with a plurality of rows of scale-holes and said arm being also provided centrally of the base thereof with a hole in line with the inner inclined edge of the other arm, and said first-named arm, being also provided on the opposite side of its outer or straight edge with inclined scale-marks, and the last-named arm being provided on its inner or inclined edge with scale-marks, substantially as shown and described.

4. A carpenter's tool or square, comprising a base-plate having a front straight edge and composed of top and bottom parts, one of which is wider at the straight edge than at the other, one end of said base-plate being also formed at a right angle to the straight edge thereof and the other end at an angle of forty-five degrees to said straight edge and two tapered arms projecting from said straight edge, said arms being separated by an angle of ninety degrees at their adjacent edges and said adjacent edges converging and intersecting adjacent to the middle of the base-plate, the outer edge of one of said arms being at an angle of forty-five degrees to the straight edge of the base-plate, and in line with the corresponding end of the base which is similarly formed, the outer edge of the other arm being at an angle of ninety degrees to the straight edge of the base-plate, and in line with said end of the base-plate which is similarly formed, substantially as shown and described.

5. A carpenter's tool or square, comprising a base having a front straight edge and composed of top and bottom parts, one of which is wider at the straight edge than at the other, one end of said base-plate being also formed at a right angle to the straight edge thereof and the other end at an angle of forty-five degrees to said straight edge and two tapered arms projecting from said straight edge, said arms being separated by an angle of ninety degrees at their adjacent edges and said adjacent edges converging and intersecting adjacent to the middle of the base-plate, the outer edge of one of said arms being at an angle of forty-five degrees to the straight edge of the base-plate, and in line with the corresponding end of the base-plate which is similarly formed, the outer edge of the other arm being at an angle of ninety degrees to the straight edge of the base-plate, and in line with said end of the base-plate which is similarly formed, the outer edge of the last-named arm being also provided at both sides with inclined or diagonal scale-marks, substantially as shown and described.

6. A carpenter's tool comprising a base having a straight edge and an arm projecting therefrom, and provided with a plurality of scale-holes arranged longitudinally thereof, said base being wider at one side than at the other, substantially as shown and described.

700,034. METHOD OF MAKING METAL WHEELS. BENJ. H. FLETCHER, Davenport, Iowa, assignor to Dittman Metal Wheel Company, a Corporation of Illinois. Filed Aug. 10, 1901. Serial No. 71,501. (No model.)

Claim.—1. In the method of making metal wheels, forcing a spoke simultaneously to both the hub and the rim by forcing the outer material of the spoke in the form of an integral shoulder into engagement with the adjacent member of the wheel without disturbing the interior of the spoke.

2. In the method of making metal wheels, forcing the outer material of the spoke into engagement with the adjacent member of the wheel without disturbing the interior of the spoke.

3. In the method of making metal wheels, coupling up the external material of the spoke in the form of a shoulder into forcible engagement

with the adjacent member of the wheel without disturbing the interior of the spoke.

4. In the method of making metal wheels, crimping up the external material of the spoke into forcible engagement with the outer side of the hub without disturbing the interior of the spoke.

5. In the method of making metal wheels, forcing the external material of the spoke against both the inner side of the rim and the outer side of the hub without changing the length of the spoke between the rim and hub.

6. In the method of making metal wheels, upsetting the end of the spoke and simultaneously forcing up the material of the spoke against the adjacent member of the wheel without changing the length of the spoke between the rim and hub.

7. The method of making metal wheels, which consists in assembling in proper relation the hub, rim and spoke and simultaneously upsetting the outer ends of the spoke and forcing the material of the spoke against the inner side of the rim and outer side of the hub without changing the length of the spoke between the rim and hub.

8. In the method of making metal wheels, providing a hub, rim and a spoke with a thickened or enlarged portion, and crimping up this thickened portion of the spoke into forcible engagement with the adjacent member of the wheel without disturbing the interior of the spoke or changing its length between the rim and hub.

9. In the method of making metal wheels, providing a hub, rim and a spoke with a thickened portion and an external shoulder, crimping up the thickened portion, and jamming up the shoulder into engagement with the hub and rim respectively without reducing the length of the spoke between the rim and hub.

10. The method of making metal wheels which consists in providing a rim having holes, a hub having holes, and a spoke having a thickened portion and a shoulder, passing the thickened end of the spoke through a hole in the hub, upsetting the outer ends of the spoke against the outer side of the rim and the inner side of the hub respectively, jamming up the shoulder on the spoke at the inner side of the rim, and crimping up the outer material of the spoke against the outer side of the hub in the form of a shoulder.

11. In the method of making metal wheels, providing a rim, a hub and a spoke, heating the end of the spoke and covering the same to the hub and rim while heated, by forcing the outer material of the spoke in the form of a shoulder into engagement with the adjacent member of the wheel without disturbing the interior of the spoke.

700,026. MACHINE FOR MAKING METAL WHEELS. BEN. BERNHART, Des Moines, Iowa, assignor to International Metal Wheel Company, a Corporation of Illinois. Filed Aug. 20, 1901. Serial No. 70,202. (No model.)

Claim.—1. In a machine of the type described, means for forcing the external material of the spoke at a point between the hub and rim,

against the adjacent member of the wheel without disturbing the interior material of the spoke, substantially as described.

2. In a machine of the type described, the combination with a device adapted to engage the spoke between the hub and rim, of means for moving said device along the spoke and in relation to the same, and means for so engaging the said device with the spoke that only the external material of the spoke will be displaced in the form of a shoulder against the adjacent member of the wheel.

3. In a machine of the type described, the combination with means for forming a head or shoulder on the end of the spoke, of means for forcing the external material of the spoke at a point between the hub and rim in engagement with the adjacent member of the wheel without disturbing the interior of the spoke, substantially as described.

4. In a machine of the type described, the combination with means for forming heads on the opposite ends of the spoke respectively outside the rim and inside the hub, of means for forcing the external material of the spoke between the hub and the rim, into engagement with the adjacent member of the wheel without disturbing the interior material of the spoke.

5. In a machine of the type described, the combination with mechanism adapted to act on the end of the spoke, of cooperating mechanism arranged to act on the spoke between the hub and the rim, means for moving said mechanism along the spoke, and means for so engaging said cooperating mechanism with the spoke that only the external material of the same will be displaced.

6. In a machine of the type described, the combination with head-on adapted to upset the ends of the spoke respectively outside the rim and inside the hub, of means for jamming a previously-formed shoulder on the spoke against the rim, and means for crimping up the outer material of the spoke against the outer side of the hub.

7. In a machine of the type described the combination with head-on movable inward toward the ends of the spoke, of devices adapted to grasp the spoke at the outer side of the hub and inner side of the rim, and means for moving said devices outward in opposite directions respectively toward the inwardly-moving head-on.

8. In a machine of the type described, the combination with a heading-tool and means for moving the same against the end of the spoke, of a device adapted to embrace the spoke between the hub and the rim and adjacent to the heading-tool, means for moving the said device outward toward the head-on, and in relation to the spoke and means for so engaging the said device with the spoke that only the external material will be displaced.

9. In a machine of the type described, the combination with means for holding the hub with its axis horizontal, of means for supporting the rim in a vertical position around the hub, devices for covering the spoke to the rim and hub, and means for moving said devices bodily horizontally in position to act on the spoke.

10. In a machine of the type described, a hub-holder comprising relatively movable rings adapted to engage the ends of the hub.

11. In a machine of the type described, the combination with a containing-frame, of two cooperating hub-holding members mounted between two to two, means for adjusting said members to and from each other and for fixing them in their adjusted positions to accommodate hubs of different lengths, and independent means for moving said members to and from each other, to admit of the insertion and removal of the hub, substantially as described.

12. In a machine of the type described, a hub-holder comprising two cooperating members adapted to grasp and hold the hub between them, said members being adjustable to and from each other and also in a direction transversely of the axis of the hub.

13. In a machine of the type described, a hub-holder comprising two cooperating members adjustable bodily in the direction of the axis of the spoke.

14. In a machine of the type described, the combination of two cooperating members adapted to hold the hub between them, means for adjusting said members to and from each other, means for adjusting them also in the direction of the axis of the spoke, and means for moving them to and from each other independently of the adjusting means.

15. In a machine of the type described, the combination with means for supporting the hub in a horizontal position, of a relatively movable support on which the rim is adapted to rest in a vertical position, and means for moving said support vertically to adjust the rim bodily transversely of the axis of the hub.

16. In a machine of the type described, the combination with means for supporting the hub, of means for supporting the rim around the same, and means for adjusting bodily the position of the rim in a direction transversely of the axis of the hub.

17. In a machine of the type described, the combination with means for supporting the hub, of a roller adapted to support the base of the rim,

and means for raising and lowering said roller to adjust the position of the rim with relation to the hub.

18. In a machine of the type described, the combination with means for supporting the base of the rim, of an adjustable stop device for supporting the side of the rim.

19. In a machine of the type described, the combination with means for supporting the rim, of a pin adapted to enter a hole in the rim to steady the same.

20. In a machine of the type described the combination with means for supporting the rim, of a pin adapted to enter a hole in the same and means for moving said pin to and from the rim.

21. In a machine of the type described, the combination with means for supporting the rim, of a pin adapted to enter a hole in the same, and movable from one side of the rim to the other, so as to enter either one of two holes in the rim.

22. In a machine of the type described, the combination with a support for the base of the rim, of a stop adapted to be engaged by the side of the rim, and a pin adapted to enter a hole in the rim.

23. In a machine of the type described the combination with means for supporting the rim, of a pin adapted to enter a hole in the rim, said pin being movable to and from the rim and also from side to side.

24. In a machine of the type described, the combination of a clamp adapted to close on the spoke between the hub and the rim, means for closing the same on the spoke, means for subsequently moving the clamp bodily toward the end of the spoke and in relation to the same and means for so regulating the pressure of the clamp that only the outer material of the spoke may be displaced.

25. In a machine of the type described the combination of heading-tools movable toward each other, of clamps movable outward toward the head-on, a cylinder and a piston therein, and operative connections between the piston and the head-on and between the piston and clamps, for operating them simultaneously.

26. In a machine of the type described, the combination with clamping devices movable outward from each other, of an operating-head movable between said clamps.

27. In a machine of the type described, the combination of clamps movable outward from each other, of means for moving one a greater distance than the other.

28. In a machine of the type described, the combination of clamps movable outward and inward with inclined adjacent surfaces, of an operating-head provided with inclined surfaces adapted to engage those on the clamps, one of the surfaces on the head being of a greater inclination than the other.

29. In a machine of the type described the combination with movable head-on adapted to act on the ends of the spoke, of clamping-jaws adapted to close on the spoke, a cylinder, a piston therein operatively connected with the head-on, a second cylinder situated within the first cylinder and open at its rear to the pressure in front of the piston, a piston in second cylinder, operative connections between this piston and the clamps formed to close the clamps on the extension of the piston, the first cylinder having a constant pressure in front of its piston and in rear of the second piston, means for admitting a high pressure to the first cylinder in rear of its piston, and means for admitting a high pressure to the second cylinder in front of its piston.

30. In a machine of the type described, the combination of a cylinder, a piston therein, spoke-holding devices operated by the advance of the piston, means for admitting a constant pressure in front of the piston, means for admitting a high pressure in rear of the same, a second cylinder situated in the first with its rear and open to the constant pressure, a piston in said second cylinder, spoke-clamping devices operated by the retraction of the second piston, and means for admitting a high pressure in front of the second piston.

31. In a machine of the type described, the combination with clamping-jaws movable bodily in a direction transversely of their clamping movement, of a cylinder and piston, a device controlled by the movement of the piston for closing the jaws, and a jointed connection between the same and the piston; whereby the jaws may be moved bodily with relation to the cylinder.

32. In a machine of the type described, the combination with means for supporting the hub and rim, of spoke-holding devices, and means for adjusting the same bodily around an axis transversely of the axis of the hub.

33. In a machine of the type described, the combination with means for supporting the hub with its axis horizontal and the rim vertical, of spoke-holding devices, and means for adjusting the same bodily around a vertical axis.

34. In a machine of the type described, the combination with means for supporting the hub and rim, of a plurality of spoke-holding devices on opposite sides of the same, and means for operating them alternately to fasten alternately the spokes to the hub and rim in one cycle.

35. In a machine of the type described, the combination with means for supporting the hub and rim, of a plurality of spoke-holding devices on opposite sides, and means for adjusting one with relation to the other on an axis transverse to that of the hub.

36. In a machine of the type described, the combination with means for supporting the hub and rim, of a plurality of spoke-holding devices on opposite sides of the same, and means for adjusting said devices independently on axes transverse to that of the hub.

37. In a machine of the type described, the combination with means for supporting the hub, rim and spoke, of two alternately-acting spoke-holding devices on opposite sides of the hub, and means for moving them independently to and from each other.

38. In a machine of the type described, the combination with a heading device adapted to act on the end of the spoke, and means for moving the same to upset the end of the spoke, of a device adjacent them adapted to act on the spoke near its end, and means for moving said heading device independently of its upsetting movement and in relation to the other device to an inoperative position to widen the space between it and the said device.

39. In a machine of the type described the combination of a main frame, standards rising therefrom, tables contained by said standards and adjustable thereon around vertical axes, slides mounted on the tables and movable to and from each other, opposing spoke-holding devices mounted on the slides, and means for supporting the hub, rim and spoke between said devices.

700,026. GAS-METER. ROBERT E. BARNES, Brooklyn, N. Y., assignor of one-fourth to Louis A. Steinhilber, Brooklyn, N. Y. Filed Feb. 4, 1902. Serial No. 20,115. (No model.)

Claim.—1. A gas-meter having a valve for controlling the flow of gas through the meter, a ported cast for the latter, said cast being set with its face out of a horizontal plane, and inlet and outlet gas-paues communicating with the ports in said cast, the inlet-paues for the gas being disposed below the outlet-paues for the gas, whereby the liquid of condensation will flow through the ports and by the valve from the outlet to the inlet without cooling the valve.

2. A gas-meter having a gas-chamber which extends below the diaphragm-chamber of the meter, valves at the lower part of said gas-chamber, ported valve-casts for said valves, said casts having their faces at an angle to a horizontal plane, an inlet for the gas opening into the gas-chamber below the level of the valve-controlled ports, and gas-outlets disposed above said ports in a manner to prevent the cooling of the valves by the accumulation of water of condensation about the same.

3. A gas-meter having its gas-inlet at a point below its diaphragm-chamber, a gas-chamber receiving gas from said inlet, and ported valve-casts in said chamber and below the diaphragm-chamber, slide-valves on said casts, mechanism for operating said valves for controlling the flow of gas through the meter, and conduits leading from the ports in the valve-casts to the gas-outlet of the meter and to the respective diaphragm-chambers, said conduits being below the said chamber.

4. A gas-meter having a diaphragm and diaphragm-chamber for measuring the gas, a gas-chamber the bottom of which is below the bottom of the diaphragm-chamber, an inlet for gas to the gas-chamber, outlets for gas from said chamber, said outlets being disposed above the level of the inlet so that liquid may flow from the former down to the latter without cooling the passage from one to the other, a valve controlling said

outside, and mechanism between the valve and diaphragm whereby the latter actuates the former.

700,087. **MURRAY-ALARM FOR SAFES.** BRANK J. MURRAY, Waverly, Ohio. Filed Dec. 10, 1906. Serial No. 66,091. (No model.)

Claim.—1. A device of the class described, having walls forming a closed passage-way leading to a safe or vault, a movable platform within said passage-way, an alarm mechanism controllable by the platform, a door arranged at the entrance to the passage-way, and means actuated by the opening of the door to depress the platform.

2. A device of the class described, comprising a protected passage-way, a movable floor therein, a door having a yieldable flap adapted to engage with said floor, and alarm device controllable by said floor.

3. A device of the class described, having a passage-way leading to a safe or vault, a platform therein, alarm device actuated by the platform, a door at the entrance to the passage-way, and means actuated by opening the door to set the alarm device into action.

4. In a device of the class described, the combination of a movable platform, a rock-shaft having a sector, a lever engaging with said sector and controllable by the platform, and alarm device actuated by movement of said rock-shaft.

5. In a device of the class described, the combination of a platform, a rock-shaft having a contact-arm engaged to make and break an alarm-circuit, a motor on the rock-shaft, and a lever adapted to engage with the motor.

6. In a device of the class described, the combination of a movable platform, a rock-shaft having a spring-controlled arm, a contact arranged to engage with said arm, a motor on the rock-shaft, a lever arranged to engage with the motor, and alarm device actuated by the rock-shaft.

7. In a device of the class described, the combination with a rock-shaft and a lever, of a platform, a trip-lever in operative relation to the platform and adapted to engage with the first-named lever, and alarm device actuated by the rock-shaft.

8. In a device of the class described, the combination of a rock-shaft provided with a sector, a lever arranged to engage with the sector, a ratchet-wheel and a pressure-plate carried by said lever at opposite ends thereof, a hinged movable platform, cambed device for said platform, and means actuated by said platform to engage the pressure-plate or the ratchet-wheel and adapted to turn the rock-shaft so as to actuate said alarm device.

700,088. **STEP-LANDER.** HERBERT L. FINELL, Boston, Mass. Filed Mar. 10, 1908. Serial No. 66,208. (No model.)

Claim.—1. A lander-step-indeh comprising two side rails, joined together at proper intervals by a series of horizontal upholding-

steps, the ends of which are inserted in grooves in the rails, and secured and reinforced by offset binding-covers passed up to their heads through the rails below and parallel with the under sides of the steps, and threaded into the eyes of bolts inserted in and projecting from the steps, and by which means the rails and steps are detachably drawn together and their joints braced and reinforced substantially as specified.

2. The combination of upwardly-bolting side rails R, R, having grooves or recesses in their inner faces; steps Q, Q, having their ends inserted in the recesses and bearing against the interior of the same; eye-bolts D, riveted to holes near the ends of the steps with their threaded eyes projecting from the upper sides thereof; and binding-covers E extended through the rails parallel with the under sides of the steps, and offset therefrom to enter the threaded eye-bolts, while their heads H pass against the outer faces of the rails, through interspersed washers F, whereby the separable joints of the rails and steps are strongly reinforced and braced; substantially as specified.

700,089. **ATTACHMENT FOR FINGER-BARS OF MOWERS OR HARVESTERS.** WILLIAM SATTENHAIN, Keweenaw, Wis. Filed May 1, 1908. Serial No. 66,209. (No model.)

Claim.—1. In combination with the finger-bar and guards of a mower or harvester, a series of castings, provided with longitudinal slots, these pivotally attached to the forward ends of said castings, and provided with backward-extending oblique arms with spring connections to said castings, and bolts longitudinally adjustable in said slots and provided with means for the retraction of the points or forward ends of said guards.

2. In combination with the finger-bar and guards of a mower or harvester, a series of castings, provided with longitudinally-recessed upper faces, and longitudinal slots therethrough, these pivotally attached to the forward ends of said castings, and provided with backward-extending oblique arms with spring connections to said castings; clamps or castings fitted to said castings, each clamp or casting having a hole therethrough; adjustable bolts, each bolt having a head and a control opening therethrough, and a screw-threaded shank adapted to pass through said hole in the clamp or casting, and through the corresponding slot in the casting to which said clamp or casting is secured, for the retraction of the points or forward ends of said guards, and nuts on each of said bolt-shanks for securing the same in place in the desired adjustment, whereby said castings are adapted for use in supporting the forward ends of said guards, irrespective of the length or angular projection of the latter.

3. In combination with the finger-bar and guards of a mower or harvester, a series of castings, with clamps supported on said castings, and held against lateral movement by the upper edges thereof, for receiving the points or forward ends of said guards, and bolts for securing said parts together.

700,080. **HOES OR POTATO PLANTER.** CHARLES E. GARDNER, Newburgh, N. Y. Filed Mar. 11, 1908. Serial No. 67,708. (No model.)

Claim.—1. The combination with a suitable framework having two drive-wheels, of a hopper; a seed-wheel mounted adjacent to the

hopper and having means to receive the seed from the hopper; and a crank connection between the seed-wheel and the drive-wheel whereby the seed-wheel is oscillated to take the seed into the said pockets and throw it upwardly; substantially as specified.

2. In a seed-planter, a suitable hopper; a seed-wheel mounted adjacent to the hopper and having means to receive the seed from the hopper; and means for oscillating the seed-wheel to take seed into said pockets and throw it upwardly and outwardly; substantially as specified.

3. In a seed-planter, a seed-wheel mounted for oscillation upon a pivot and having pockets below the pivot; means for conducting the seed to said pockets; and means for oscillating the seed-wheel to throw the seed upwardly; substantially as specified.

4. A seed-planter comprising the combination with a suitable framework having traction drive-wheels and having a furrow-opener and a seed-covener, of a hopper; a seed-wheel mounted adjacent to the hopper and having means to receive the seed from the hopper; a crank-shaft connected to the drive-wheel; a crank-pin upon the seed-wheel; a connecting-rod connecting the crank-shaft pin to the seed-wheel crank-pin, the crank-pin bearing in one end of the connecting-rod being slotted to give a jerky motion so that as the crank-shaft rotates the seed-wheel is oscillated to take seed from said hopper into said pockets and throw it upwardly and outwardly in both directions; and conveyers to receive said seed and carry it to the furrow behind said furrow-opener; substantially as specified.

700,081. **STENCIL-PRINTING APPARATUS.** DAVID GUTHRIE, London, England. Filed Feb. 1, 1908. Serial No. 66,164. (No model.)

Claim.—1. The combination with stencil-printing apparatus having two ink-rollers, a pair of endless bands around said rollers, a presser sheet and a stencil attached to said bands, waver or distributing rollers in contact with the ink-rollers, and a flexible impression-roller, of spring-supported carriers for said rollers, arms supporting said carriers, a shaft on which said arms are fixed, links pin-jointed to the carriers and end frames for controlling the motion of the carriers, a pin on one of said arms, a hook on a lifting-plate to act with said pin, and a rising and falling plate to which said lifting-plate is pivoted to lift the impression-roller to the printing position, substantially as herein set forth.

2. The combination with stencil-printing apparatus having two ink-rollers, a pair of endless bands around said rollers, a presser sheet and a stencil attached to said bands, a clamp on said bands to hold one end of a stencil the body of which is held smoothly over and adheres to the surface of the inked presser sheet, and waver or distributing rollers in contact with the ink-rollers, of means for automatically giving to-and-fro endwise motion to said waver-roller, a flexible impression-roller, and a paper-stop, both automatically operated, substantially as herein set forth.

3. The combination with stencil-printing apparatus having two ink-rollers, a pair of endless bands around said rollers, a presser sheet and a stencil attached to said bands, waver or distributing rollers in contact with the ink-rollers, of a flexible impression-roller, a paper-stop against which the paper to be printed is placed, and means for automatically placing said stop in position for use and removing it therefrom, substantially as herein set forth.

4. The combination with stencil-printing apparatus having two ink-rollers, a pair of endless bands around said rollers, a presser sheet and a stencil attached to said bands, waver or distributing rollers in contact with the ink-rollers, of a flexible impression-roller, and means for varying the time at which the impression-roller and paper-stop come into operative position without changing the time at which the impression-roller leaves the printing position, substantially as herein set forth.

5. The combination with stencil-printing apparatus having two ink-rollers, a pair of endless bands around said rollers, a presser sheet and a stencil attached to said bands, waver or distributing rollers in contact with the ink-rollers, of a flexible impression-roller, a paper-stop, and means for throwing the impression-roller and paper-stop out of operative position while the ink-roller and waver rollers are left free to revolve, substantially as herein set forth.

6. The combination with stencil-printing apparatus having two ink-rollers, a pair of endless bands around said rollers, a presser sheet in contact with the ink-rollers, and a stencil supported by said bands and presser sheet, of spring-supports to the upper ink-roller to maintain the tension of the endless bands, substantially as herein set forth.

7. The combination with stencil-printing apparatus having two ink-rollers, a pair of endless bands around said rollers, a presser sheet and stencil attached to said bands, waver or distributing rollers in contact with the ink-rollers, of blocks in which the waver-roller arms are supported at each end, open-ended slotted levers in which said blocks are carried, springs connecting together each pair of blocks to keep the waver-roller in constant contact with the ink-rollers when the machine is in use, a lever mounted on an axle and giving motion to one of said slotted levers, and an eccentric for giving motion to said slotted lever, substantially as herein set forth.

8. The combination with stencil-printing apparatus having two ink-rollers, a pair of endless bands around said rollers, a presser sheet and a stencil attached to said bands, waver or distributing rollers, of wedge-shaped plates placed between the axes of the waver-rollers in position to be depressed by the cover being placed over the machine, thereby automatically separating the waver-rollers from the ink-rollers, substantially as herein set forth.

9. The combination with stencil-printing apparatus having two ink-rollers, a pair of endless bands around said rollers, a presser sheet and a stencil attached to said bands, waver or distributing rollers in contact with the ink-rollers, on impression-roller, and a paper-stop, of a guided rising and falling plate, a lifting-plate pin-jointed to said guided plate, a dependent stoppiece pin-jointed to said lifting-plate, a spring attached to said lifting-plate and to one of the levers carrying the impression-roller, and a wedge-piece operated by an eccentric to lift said guided plate to give the required motion to the impression-roller and paper-stop in the normal working of the machine, substantially as herein set forth.

10. The combination with stencil-printing apparatus having two ink-rollers, a pair of endless bands around said rollers, a presser sheet and a stencil attached to said bands, waver or distributing rollers in contact with the ink-rollers, and a flexible impression-roller, of spring-supported carriers for said rollers, arms supporting said carriers, a shaft on which said arms are fixed, links pin-jointed to the carriers and end frames for controlling the motion of the carriers, a pin on one of said arms, a hook on a lifting-plate to act with said pin, and a rising and falling plate to which said lifting-plate is pivoted to lift the impression-roller to the printing position, substantially as herein set forth.

11. The combination with stencil-printing apparatus having two ink-rollers, a pair of endless bands around said rollers, a presser sheet and a stencil attached to said bands, waver or distributing rollers, and an impression-roller, of a paper-stop, arms carrying said stop, slots in said arms, a shaft passing through said slots, pins in sides of said arms, cam-floated levers fixed on said shaft to act against said pins, springs attached to said arms and to the end frames to pull the stop forward, a rising and falling plate, an incline and a stoppiece on said plate, and a roller on one of the cam-floated levers acted upon by said incline and stoppiece to operate the paper-stop, substantially as herein set forth.

12. The combination with stencil-printing apparatus having two ink-rollers, a pair of endless bands around said rollers, a presser sheet and a stencil carried by said bands, waver or distributing rollers, and a flexible impression-roller, of a paper-stop, arms carrying said stop, slots in said arms, a shaft passing through said slots, and cam-floated levers acting against said arms to first raise the stop slightly above the impression-roller and then to push said stop back, substantially as herein set forth.

13. The combination with stencil-printing apparatus having two ink-rollers, a pair of endless bands around said rollers, a presser sheet and a stencil attached to said bands, waver or distributing rollers, and an impression-roller, of a sliding bar, a screw to move said bar back and forth to adjust the time of raising the impression-roller, a lever pin-jointed to said bar, a bar pin-jointed to said lever and operated by an eccentric to give motion thereto, a wedge-piece pin-jointed to said lever, and a rising and falling plate acted upon by said wedge-piece to raise the impression-roller to the printing position, substantially as herein set forth.

14. The combination with stencil-printing apparatus having two ink-rollers, a pair of endless bands around said rollers, a presser sheet and a stencil attached to said bands, waver or distributing rollers, on impression-roller, and a paper-stop, of a slotted bar, a lifting-plate giving motion to the impression-roller and paper-stop and to which said slotted bar is pivoted, a shaft, a crank-pin on said shaft acting within said slot, and a weighted lever to operate said shaft so as to enable the impression-

roller and paper-strip to be put in or out of operation, substantially as herein set forth.

15. The combination with stencil-printing apparatus having a pair of inking-rollers, endless bands passing around said rollers, and a porous sheet and stencil removably attached to said bands, of a strengthened edge on the porous sheet, keyhole-slots in said strengthened edge, a pocket of stronger material attached to the other edge of said porous sheet, and holes perforated along the edge of said pocket, substantially as herein set forth.

16. The combination with stencil-printing apparatus having a pair of inking-rollers, endless bands passing around said rollers, and a porous sheet and stencil removably attached to said bands, of a bar fixed to said bands, studs on said bar, a strengthened edge on the porous sheet, keyhole-slots in said strengthened edge, a pocket of stronger material attached to the other edge of said porous sheet, holes perforated along the edge of said pocket, a removable bar having rounded projections thereon to pass through said holes, and springs to connect each removable bar with the endless bands, substantially as herein set forth.

17. The combination with stencil-printing apparatus having a pair of rollers, endless bands passing around said rollers, and a porous sheet, and stencil removably attached to said bands, of a clamp-base fixed to the endless bands, and a trough-shaped cover removably attached to said base to secure one edge of the stencil, substantially as herein set forth.

700,083. WHEEL-HUB. LEON T. GUNN, New York, N. Y., assignor to Vehicle Equipment Company, Brooklyn, N. Y., a Corporation of New Jersey. Filed Sept. 11, 1901. Serial No. 74,986. (No model.)

Claim.—A wheel-hub comprising in combination a single casing A, a tubular wooden core B driven or pressed into the same, the outer end of said casing having an opening equal in diameter to that through the wooden core, and the inner end being of greater diameter than the core, to afford two supports for a bearing, and a box or bearing extending through the hub and supported at each end by the casing, as set forth.

700,088. RENDERING AND DRYING APPARATUS. JAMES GLAZIER, Brooklyn, N. Y. Filed June 2, 1901. Serial No. 68,905. (No model.)

Claim.—1. In a combined rendering and drying apparatus the combination of a casing, a rotary hollow shaft contained within the said casing, hollow arms carried by the said shaft delivering fluid to the interior of said casing, means for rotating the said shaft and a removable head and screen and an outlet for fluid, which may be rendered out, the said outlet being adapted to remain constantly open during the rendering and drying operations.

2. In an apparatus adapted for rendering or drying the combination of a casing, rotary means for introducing and distributing heated fluid into contact with the material to be treated, a sleeve at or near the bottom of said casing, a run-off duct or passage receiving melted fat, &c., and means for removably securing the sleeve or screen in the casing.

3. In an apparatus adapted for rendering or drying the combination of a casing, a hollow shaft, hollow arms carried on the said shaft and communicating therewith and delivering fluid to the interior of said casing, and stirring-blades carried by the said arms.

4. In an apparatus adapted for rendering or drying the combination of a casing, a rotary means for delivering fluid to the interior of said casing, and into contact with the material to be treated, and a removable head and a screen.

5. In an apparatus adapted for rendering or drying the combination

of a suitable casing, a rotary combined stirring and fluid-delivering apparatus contained therein, the said casing being entirely unobstructed except for the said rotary apparatus, a suitable sleeve or screen and means for movably supporting the sleeve or screen whereby the charge may be removed from the vessels.

6. In an apparatus adapted for rendering or drying, the combination of a casing, a hollow shaft with means for revolving the said hollow shaft, laterally-projecting fluid-conducting means carried by the said shaft, adapted to deliver fluid to the interior of said casing at points remote from the said shaft, the said laterally-projecting fluid-conducting means carrying means for effecting a stirring action on the mass.

7. In an apparatus adapted for rendering or drying, the combination of a casing, a hollow rotary fluid-distributing device, adapted to distribute fluid into the said casing at the points remote from the center of rotation of the said fluid-distributing device, a liquid-outlet and a sleeve contained within the casing whereby fluid may be introduced into the said casing at places throughout the mass contained in said casing whereby a pressure may be brought to bear upon the said mass at widely-different points in order to force moisture out of said mass through the fluid-delivery orifices.

700,084. PHOTOGRAPHIC-PLATE HOLDER. JAMES GOODMAN, Rochester, N. Y., assignor to Rochester Optical & Camera Co., Rochester, N. Y., a Corporation of New York. Filed Jan. 17, 1902. Serial No. 90,198. (No model.)

Claim.—1. In a photographic-plate holder, the combination with the plate-holder frame and the slide provided at its outer end with a depending flange, of a spring-catch fixed to the front end of the plate-holder frame and projecting beyond the latter, said catch being arranged to automatically yield to said flange when the slide is pushed into place and having a projecting end adapted to be engaged by the same hand employed to withdraw the slide, whereby the catch may be released and the slide withdrawn at one movement of the hand, substantially as described.

2. In a photographic-plate holder, the combination with the plate-holder frame and the slide provided at its end with a depending flange, of a spring-catch fixed to the front end of the plate-holder frame and projecting beyond the latter, said catch comprising a spring-finger provided with a beveled end adapted to be engaged by and thrust aside by the flange on the slide and with a corrugated portion arranged to snap under the lower edge of said flange and lock the slide in place, substantially as described.

3. In a photographic-plate holder, the combination with the plate-holder frame and the slide provided at its outer end with a depending flange, of a spring-catch fixed to the front end of the plate-holder frame and projecting beyond the latter, said catch comprising a spring-finger provided with a beveled end adapted to be engaged by and thrust aside by the flange on the slide and with a corrugated portion arranged to snap under the lower edge of said flange and hold the slide in place, and a transverse strip fitted in the front end of the plate-holder frame and longitudinally grooved on its under side, the said spring-finger being provided at its inner end with a flat head fitted in said groove, substantially as described.

4. In a photographic-plate holder, the combination with the plate-holder frame, of a light-enclosing device, consisting of a transverse strip fitted in the front end of the plate-holder frame and provided on its upper side with a light-enclosing brush, and having a groove on its under side, of the slide provided at its free end with a depending flange, and a spring-catch comprising a flat head fitted between the grooved portion of said strip and the bottom of the plate-holder frame and having an outwardly-projecting spring-finger arranged to engage the said flange and hold the slide in place, substantially as described.

5. In a photographic-plate holder, the combination with a plate-holder frame, of a light-enclosing device, consisting of a transverse strip fitted in the front end of the frame and provided on its upper side with a light-enclosing brush and having a groove on its under side, of a slide provided at its free end with a depending flange, and a spring-catch comprising a flat head, having two parallel wings, the rear edge of the head and the free ends of the wings having depending flanges, said head being fitted in said groove, and an integral spring-finger projecting outward from the head and arranged to engage the flange on the slide and hold the latter in place, substantially as described.

6. In a photographic-plate holder, the combination with a plate-holder frame and its slide, of a skeleton frame fitted in the plate-holder frame and comprising a rectangular sheet-metal frame provided at its opposite inner ends with integral inwardly and upwardly projecting spring-fingers, arranged to engage the under side of the plate, substantially as described.

7. In a photographic-plate holder, the combination with a metal plate-holder frame having inwardly-bent flanges, of a sheet-metal slide, and a skeleton frame, comprising a rectangular sheet-metal frame, provided with upwardly and inwardly bent flanges arranged to fit beneath the flanges of the plate-holder frame and provided at its opposite inner ends with inwardly and upwardly projecting integral spring-fingers, substantially as described.

700,085. XYLOPHONE-PLAYER. FREDERICK R. GOSMAN, Banghamton, N. Y. Filed May 14, 1894. Serial No. 69,594. (No model.)

Claim.—1. In a musical instrument, an apertured chest, a dust-bridge over which the chest passes, a series of pneumatic motors connected with the ducts of the bridge, a series of hammers, mechanism for operating the hammers, means operated by the motors for causing the hammer-operating mechanism to operate each hammer so that it will make a single stroke, an auxiliary pneumatic motor connected with the ducts of the bridge, and means operated by said motor and controlling the means operated by the first-named motors so as to cause the hammer-operating mechanism to operate each hammer so that it will make a number of strokes in quick succession, as set forth.

2. In a musical instrument, an apertured chest, a dust-bridge over which the chest passes, a series of pneumatic motors connected with the ducts of the bridge, a series of hammers, a swinging lever carried by each hammer, a movable member with which the swinging levers of the hammers are adapted to engage, means operated by the motors for holding the levers of the hammers into engagement with the movable member,

an auxiliary pneumatic motor connected with the ducts of the bridge, and means operated from said motor and controlling the time the levers of the hammers are held in the path of the movable member, as and for the purpose set forth.

3. In a musical instrument, an apertured chest, a dust-bridge over which the chest passes, a series of pneumatic motors connected with the ducts of the bridge, a series of hammers, a swinging lever carried by each hammer, a revolvable cylinder provided with projections on its periphery with which the swinging levers of the hammers are adapted to engage, means operated by the motors for moving the levers of the hammers into engagement with the projections of the cylinder, an auxiliary pneumatic motor connected with the ducts of the bridge, and means operated by the said motor and controlling the means operated by the first-named motors, as set forth.

4. In a musical instrument, an apertured chest, a dust-bridge over which the chest passes, a series of pneumatic motors connected with the ducts of the bridge, a series of hammers, pivoted and spring-pressed levers carried by the hammers, a revolvable cylinder provided with projections on its periphery with which the levers of the hammers are adapted to engage, swinging operating-levers carrying feet adapted to engage the levers of the hammers, and operated from the said motors, an auxiliary pneumatic motor, and means operated by the said motor and controlling the swinging movement of said operating-levers, as set forth.

5. In musical instruments, an automatic xylophone-player, consisting of a frame, a series of tone-producing bars carried by the frame, spring-controlled hammers for said bars, jack-levers carried by the hammers, a ribbed cylinder arranged to rest upon the jack-levers, a vacuum-chest, operating-levers for the jack-levers, actuated from the vacuum-chest, an auxiliary chest, a controlling mechanism for the operating-levers, operated from the auxiliary chest, a dust-bridge, one end of the said ducts in the bridge being connected with the vacuum-chest and others with the auxiliary chest, and means, substantially as described, for opening and closing the ducts in the said bridge, as set forth.

6. In musical instruments, the combination, with a frame, tone-producing bars carried by the frame, spring-actuated hammers for the said tone-producing bars, a rotary peripherally-ribbed cylinder, jack-levers carried by the hammers and adapted to be brought in the path of the ribs of the cylinder and carried out of the path of the same, a vacuum-pump for the vacuum-chest, an auxiliary chest, and an equalizing-pump also in communication with the vacuum-chest, of spring-controlled operating-levers, having vertical movement to and from the jack-levers connected with the hammers and capable of swinging movement over said jack-levers, operating mechanism controlled by the vacuum-chest and operating on the operating-levers, a controlling device for the operating-levers, operated from the auxiliary chest, a dust-bridge, tubular connections between one end of the ducts of said bridge and the vacuum-chest, and tubular connections between other ducts of the said bridge and the auxiliary chest, and means for opening and closing the ducts of the bridge, as described.

7. In musical instruments, the combination, with a frame, tone-producing bars carried by the frame, spring-controlled hammers for said bars, jack-levers carried by the said hammers, a peripherally-ribbed cylinder, the ribs of which are adapted for engagement with the jack-levers, a vacuum-chest having a series of upper chambers provided with diaphragms, and a lower continuous chamber, an auxiliary chest provided with a continuous diaphragm, vacuum-pumps connected with the continuous chamber of the vacuum-chest, and an equalizing-pump connected with said chamber, of spring-controlled operating-levers capable of movement to and from the jack-levers, being adapted to normally rest thereon, and also to have swinging movement over the jack-levers, said operating-levers being acted upon by the diaphragms of the vacuum-chest, a controlling device for the operating-levers, operated upon by the diaphragms of the auxiliary chest, and a dust-bridge, one end of the ducts of which have tubular connections with the upper compartments of the vacuum-chest, other of the ducts in said bridge having connection with the auxiliary chest above its diaphragm, as and for the purpose specified.

8. In a musical instrument, a dust-bridge, means for opening and closing the ducts thereof, a series of pneumatic motors connected with the ducts of the bridge, a series of hammers, pivoted and spring-pressed levers carried by the hammers, a revolvable cylinder provided with peripheral projections with which the levers of the hammers are adapted to engage, and means operated by motors for moving the levers of the hammers into engagement with the projections of the cylinder, as set forth.

9. In a musical instrument, a dust-bridge, means for opening and closing the ducts thereof, a series of pneumatic motors connected with the ducts of the bridge, a series of hammers, pivoted and spring-pressed levers carried by the hammers, a revolvable cylinder provided with peripheral projections with which the levers of the hammers are adapted to engage, spring-pressed swinging operating-levers carrying feet for engagement with the levers of the hammers, and means whereby the operating-levers are operated from the motors, as set forth.

10. In a musical instrument, a dust-bridge, means for opening and

closing the duct thereof, a series of pneumatic motors connected with the ducts of the bridge, a series of hammers, pivoted and spring-pressed levers carried by the hammers, a reversible cylinder provided with peripheral projections with which the levers of the hammers are adapted to engage, pivoted and spring-pressed opening-levers, means for operating the levers from the motors, and pivoted and spring-pressed feet carried by the operating-levers and adapted to engage the levers of the hammers, as set forth.

11. In a manual instrument, a duct-bridge, means for opening and closing the duct thereof, a series of pneumatic motors connected with the ducts of the bridge, a series of hammers, pivoted and spring-pressed levers carried by the hammers, a reversible cylinder provided with peripheral projections with which the levers of the hammers are adapted to engage, pivoted and spring-pressed angular levers, means for operating the levers from the motors, and pivoted and spring-pressed feet carried by the vertical member of the angular levers, and feet carried by the feet and adapted to engage the levers of the hammers, as set forth.

12. In a manual instrument, a duct-bridge, means for opening and closing the duct thereof, a series of pneumatic motors connected with the ducts of the bridge, a series of hammers, pivoted and spring-pressed levers carried by the hammers, means with which the levers of the hammers are adapted to engage to operate the hammers, pivoted and spring-pressed feet adapted to engage the levers of the hammers, means for operating the feet from the motors to cause them to depress the said hammer-levers, an auxiliary pneumatic motor connected with the ducts of the bridge, and means operated by the auxiliary motor for controlling the swinging movement of the said feet, as set forth.

13. In a manual instrument, a duct-bridge, means for opening and closing the duct thereof, a series of pneumatic motors connected with the ducts of the bridge, a series of hammers, pivoted and spring-pressed levers carried by the hammers, means with which the said levers are adapted to engage to operate the hammers, pivoted and spring-pressed feet adapted to engage the hammer-levers, means for operating the feet from the motors to cause them to depress the hammer-levers, an auxiliary pneumatic motor, a swinging bar operated by the auxiliary motor, and a connection between the said bar and the feet, as set forth.

14. In a manual instrument, a duct-bridge, means for opening and closing the duct thereof, a series of pneumatic motors connected with the ducts of the bridge, a series of hammers, pivoted and spring-pressed levers carried by the hammers, a reversible cylinder provided with peripheral projections with which the hammer-levers are adapted to engage, pivoted and spring-pressed feet adapted to engage the hammer-levers, means for operating the feet from the motors to cause them to depress the hammer-levers, an auxiliary pneumatic motor, a swinging bar, an angle-lever connected with the bar and operated by the auxiliary motor, and yokes extending from said bar and engaging the feet, as set forth.

700,086. FURNACE. RALPH H. COVENS, Reading, Mass. Filed July 4, 1901. Serial No. 61,364. (No model.)

Claim.—1. In an underfed mechanical stoker in which the coal is supplied to a magazine or retort extending transversely across the rear end of the furnace, a plurality of tuyers extending transversely of the furnace and rising one above the other from the front to the rear of the furnace.

2. In an underfed mechanical stoker in which the coal is supplied to a magazine or retort extending transversely across the rear end of the furnace, one or more rows of tuyers transverse to said furnace, said row or rows including a plurality of tuyers projecting beyond the remainder of the tuyers in the said row or rows, so as to produce a more thorough distribution of the air throughout the fuel and above the retort.

3. In an underfed mechanical stoker in which the coal is supplied to a magazine or retort extending transversely across the rear end of the furnace, a front air-box to which the air is supplied under pressure, a row

of tuyers connected to said box, and having one or more projecting tuyers, so as to produce a thorough distribution of the air throughout the fuel.

4. In an underfed mechanical stoker in which the coal is supplied to a magazine or retort extending transversely across the rear end of the furnace, a front air-box and a rear air-box to which the air is supplied under pressure, rows of tuyers transverse to said boxes, one or more longitudinal air-boxes connecting the two front-mentioned boxes, and one or more tuyers-bleeds connecting said longitudinal air box or boxes and having air-outlets, substantially as described.

700,087. REPEATER FOR TELEGRAPH-LINES. JAMES W. GRAY, Forter, Ind. Filed Nov. 20, 1901. Serial No. 59,306. (No model.)

Claim.—1. In a repeater, the combination of a high-resistance relay, a low-resistance relay, a battery, and a key all connected in circuit, a circuit-breaker and a resistance-coil both in shunt around said high-resistance relay, substantially as described.

2. In a repeater, the combination of a low-resistance relay-coil, a high-resistance relay-coil, a battery and a first key all connected in circuit, a resistance-coil and a circuit-breaker both in shunt around said high-resistance relay, means for operating said circuit-breaker, a second key and a battery all three of the last-mentioned devices included in circuit, substantially as described.

3. In a repeater, the combination of a low-resistance relay-coil, a first key, a battery and a high-resistance relay all connected in circuit, a resistance-coil and a circuit-breaker both connected in a shunt around said high-resistance relay-coil, a local sounder, a battery and a circuit-breaker all three connected in circuit, said circuit-breaker being arranged to be operated by said high-resistance relay-coil, substantially as described.

4. In a repeater, the combination of a first low-resistance relay-coil, a first key, a battery, and a first high-resistance relay all connected in circuit, a resistance-coil and a first circuit-breaker both connected in a shunt around said high-resistance relay-coil, a local sounder, a battery and a circuit-breaker all connected in circuit, said circuit-breaker being arranged to be operated by said low-resistance relay-coil, a second key, a battery, and a low-resistance relay-coil all four connected in circuit, said second low-resistance relay-coil being arranged to operate said first circuit-breaker, a second circuit-breaker and a resistance-coil both connected in a shunt around said second high-resistance relay-coil, said second circuit-breaker being arranged to be operated by said first high-resistance relay-coil, substantially as described.

5. In a repeater, the combination, of a first low-resistance relay-coil, a first key, a battery, and a first high-resistance relay and all four connected in circuit, a local sounder, a battery and a circuit-breaker all three connected in circuit, said circuit-breaker being arranged to be operated by said low-resistance relay-coil, a resistance-coil and a first circuit-breaker all connected in a shunt around said high-resistance relay-coil, a second low-resistance relay-coil, a second high-resistance relay-coil, a second key, and a battery all four connected in circuit, said second high-resistance relay-coil

being arranged to operate said first circuit-breaker, a second circuit-breaker, and a resistance-coil both connected in a shunt around said second high-resistance relay-coil, said second circuit-breaker being arranged to be operated by said first high-resistance relay, a local sounder, a battery and a circuit-breaker, said last-mentioned circuit-breaker being arranged to be operated by said second low-resistance relay-coil, substantially as described.

700,088. DRIVING-AXLE FOR LOCOMOTIVES. CHRISTIAN HAAKE, Berlin, Germany. Filed Nov. 27, 1901. Serial No. 59,308. (No model.)

Claim.—1. A device of the class specified, comprising a sleeve provided with wheels, an axle consisting of a plurality of sections fitted in the sleeve, and the lower ends of the axle-sections being ball-shaped and the sleeve being slotted, spherical bearings in the sleeve for said ball ends, and wedges adapted to project through said slots and to bear against said spherical bearings for the purpose of adjusting the same.

2. A device of the class described, comprising a sleeve provided with wheels, an axle consisting of a plurality of sections fitted in the sleeve and having ball-shaped inner ends, spherical bearings in the sleeve for said ball ends, and the latter having recesses in their adjacent surfaces, and the bottoms of the recesses being convex, and a body fitted into said recesses and its opposite ends being convex.

3. A device of the class specified, comprising a sleeve provided with wheels, an axle consisting of a plurality of sections fitted in said sleeve and having ball-shaped inner ends, spherical bearings in the sleeve for receiving said ball-shaped ends, pins extending through slots in the sleeve and ball-shaped ends respectively, and caps upon the sleeve covering the outer ends of said pins.

700,089. FIRE-ALARM AND DOOR-LOCK. LOUIS E. HANST, New Providence, and GEORGE S. HANST, Baltimore, Md. Filed Sept. 14, 1901. Serial No. 73,492. (No model.)

Claim.—1. In a burglar-alarm and door-lock, the combination of a holder-plate adapted to be seated between the door-casing and the door edge, and having in its rear end an open-ended slot, a base-plate having a stud with thumb-out, whereby said plate is adjustably and removably fitted to the slot of said holder-plate, said base-plate carrying an alarm mechanism and having a stop on its forward end opposing the door, a slidable tripping-rod mounted in the base-plate with its end extending through the stop and lying in the path of the door movement, and an engagement between said rod and the mechanism of the alarm mechanism effective to arrest the operation of the said mechanism when the rod is normally out and to release said mechanism when the rod is pushed back.

2. In a burglar-alarm and door-lock, the combination with the last and bell, of a holder therefor comprising a plate A provided at one end with an opening for a screw pin or bolt, and at the other end with separated members having offset points a, a, and an elongated spring c' struck up from the plate at a point intermediate of said separated members and projecting laterally therefrom, substantially as described.

3. In a burglar-alarm and door-lock, the combination with the last

and bell, of a holder therefor comprising a plate A cut away at one end to function as open-ended slot c' for a screw pin or bolt, and provided at its opposite end with separated members having offset points a, a, and an elongated spring c' struck up from the plate at a point intermediate of said separated members and projecting laterally therefrom, substantially as described.

4. In a burglar-alarm and door-lock, the combination with the last and bell, a holder therefor comprising a plate A provided with an opening for a screw pin or bolt, and at one end with a member having an offset point a, and an elongated spring c' elongated said offset point a, said spring being struck up from the plate and projecting laterally beyond the pointed member, substantially as described.

5. In a burglar-alarm and door-lock, the combination of a holder-plate A adapted to be seated between the door-casing and the door edge, a base-plate B, means for securing the base-plate in adjusted position on the holder-plate, an apertured offset portion b on the base-plate arranged to oppose the opening of the door, an alarm mechanism carried by the base-plate, said mechanism including a stop-pin c, a tripping-rod F slidably mounted on the base-plate with its end passing through the aperture in the offset portion b, and lying in the path of the door movement, a spring G secured at one end to the base-plate B and at the other end bearing against the rod F to normally retain the same in outward position, and a shoulder / on said rod adapted to cooperate with the stop-pin c of the alarm mechanism to hold the alarm mechanism inactive until the rod is forced inwardly, substantially as described.

6. In a burglar-alarm and door-lock, the combination of a holder-plate A adapted to be seated between the door-casing and the door edge, a base-plate B, means for securing the plate B in adjusted position on the holder-plate, and apertured offset portion b on the base-plate arranged to oppose the opening of the door, an alarm mechanism carried by the base-plate, said mechanism including a stop-pin c, a tripping-rod F slidably mounted on the base-plate with its end passing through the aperture in the offset portion b and lying in the path of the door movement, and a shoulder on said rod adapted to normally engage the stop-pin c of the alarm mechanism to hold said alarm mechanism inactive, but to be withdrawn from engagement therewith to release the alarm mechanism when the rod is forced inwardly, substantially as described.

7. In a burglar-alarm and door-lock, the combination with a lock and an alarm mechanism including a stop-pin c, of a support, a slidable tripping-rod F normally projecting outward into the path of the door movement, a spring G for holding the rod in position, said spring being secured at one end to the support and at its free end slidably engaging the rod to permit the movement of said rod independently of the spring, and a shoulder on the rod adapted to normally engage the stop-pin c to retain the alarm mechanism inactive but when withdrawn from engagement therewith to release the alarm mechanism when the rod is forced inwardly, substantially as described.

700,040. CIGARETTE-MACHINE. JAMES C. HANSEN-BALHAGEN, Copenhagen, Denmark. Filed June 7, 1901. Serial No. 61,544. (No model.)

Claim.—1. In a cigarette-machine, a filling mechanism comprising a spiral, and mechanism for positively actuating said spiral to impart rotary movement and axial displacement thereto; said mechanism being effective on the advancement of the filler to give both rotary movement and axial displacement to the spiral, and then to impart axial displacement only to said spiral, while on the return movement of the filler, the mechanism causes the spiral out of the cigarette and thereafter displace the spiral in the direction only of its axis.

2. A cigarette-machine having filling means comprising a wire in the form of a spiral, means for imparting movement to the said filling means, a body m, mounted transversely upon a movable slide p, to which body is fitted the cross-shaped wire p and which body is provided with a cross shaped groove a of the same pitch as the wire, in combination with a pin v projecting into said groove and capable of being at suitable moments held firm as regards the movable slide or released therefrom in such a manner that a moving and a straight motion is alternately imparted to the wire.

3. A cigarette-machine having a filling mechanism comprising a spiral feeder, a slide provided with spaced hooks, a slide-bar having a pin, yieldable arms disposed in the path of said pin and having projections in the path of the spaced hooks, and means for actuating the slide.

4. In a cigarette-machine, a filling mechanism comprising a spiral feeder, and an actuating mechanism to impart rotary and axial movement to said spiral feeder, said actuating mechanism including a cam-governed reversible member, said spiral feeder having its revolution corresponding in pitch to the groove of said reversible member.

5. In a cigarette-machine, a filling mechanism comprising a spiral feeder and an actuating mechanism therefor, said mechanism having a reversible and slidable member which carries the spiral feeder, means for imparting rotary movement to the carrier member, and means for rotating

ing the carrier member simultaneously with its slidable travel; said rotating means being effective only for a part of the travel of the carrier member.

6. In a cigarette-machine, a filling mechanism comprising a spiral feeder and an actuating mechanism therefor, said mechanism including a movable base, a rotatable carrier member mounted on the base and having the feeder movable therewith, means for giving reciprocating movement to the base, and means for intermittently rotating the carrier member.

7. A cigarette-machine having a filling means, comprising a device in the form of a spiral, adapted to enter and carry the filler, and means for imparting a rotary motion to the said device.

8. A cigarette-machine having a filling means, comprising a device in the form of a spiral, adapted to enter and carry the filler, and means for imparting alternately a longitudinal and a rotary motion to the said device.

9. A cigarette-machine comprising a base having an opening therein, a slide movable in the opening and carrying a device in the form of a spiral adapted to enter and carry the cigarette-filling mechanism for imparting a rotatable and endwise movement to said spiral, a mold, means thereon for holding a cigarette tube or wrapper, and means for imparting movement to the slide to pass the filling into the cigarette tube or wrapper.

10. In a cigarette-machine, a filling mechanism comprising a rotatable and slidable carrier member, a filler spiral thereon, stop devices adjacent to the path of the carrier member, and a slidable element movable with the carrier member and having means arranged to coast with the stop devices.

11. In a cigarette-machine, the combination of a cam-grooved carrier member having a spiral feeder, means to impart slidable movement to said carrier member, yieldable stops disposed in the path of projection from said carrier member, and a slidable bar mounted to travel with the carrier member for a limited distance and having means engaging with the groove of said member and other projections adapted to engage with the stop devices.

12. In a cigarette-machine, the combination of a shaping and forming mold having a movable member, a filler mechanism including a spiral feeder, mechanism to impart a traveling motion to said filler mechanism, and means for opening and closing the mold on the rotation of the filler mechanism.

13. In a cigarette-machine, the combination of a mold, a filler mechanism including a spiral feeder which is adapted to be thrust with a twisting movement into said mold, and a common mold and filler actuating mechanism having operative connection with the filler mechanism to impart slidable travel thereto and an operative connection with the mold to open and close the latter.

14. In a cigarette-machine, the combination with a forming and shaping mold, of a filler mechanism having a spiral feeder and means for giving a twisting movement to said feeder when advanced into the mold, mechanism for imparting traveling movement to the feeder mechanism and means for opening and closing the mold.

700,041. **WHEEL**. WILLIAM E. HANDELIN, Thompson, Pa. Filed Dec. 13, 1901. Serial No. 33,083. (No model.)

Claim.—In a wheel, a camshaft part and its arm, a bell-crank pivoted to the part near the bottom, a cam-block slidable with relation to one of the rails of a railway-track, a yoke secured to the block, a link connected to the yoke and pivotally connected to the bell-crank, means whereby the bell-crank operates to lift the camshaft-arm and move the block close to the rail, a tripping-lever carried by the engine operated by contact with the cam-block, a pipe tapped in the main-pipe of an air-brake system, a whistle on the pipe, a valve in the pipe and a connection from the tripping-lever to the valve whereby said valve is opened when the lever is tripped as and for the purpose described.

700,042. **FOLDING SUGAR-BED**. RICHARD C. HARRINGTON, Denver, Colo. Filed Apr. 9, 1901. Serial No. 33,084. (No model.)

Claim.—1. In a bed-bed, the combination with a pair of ends, each composed of a stationary and an adjustable section hinged together whereby the said adjustable section may be extended in alignment with the stationary section and arranged at right angles to said stationary section, of a vertically-extending support arranged between the stationary section of the ends, an adjustable rest adapted to engage over and upon the top of said support when the said rest is in a lowered position, means for suitably hinging one side of the rest to the support to permit of elevating the said rest, an adjustable back adapted to extend over and upon the top of the said support when the said back is in a lowered position, means for suitably hinging the back to the said support to permit of vertically adjusting the said back, an elongated clasp secured to the stationary section of the ends, clasp connected to the rest and engaging in the clasp of the ends for supporting the rest when in a lowered position, and means carried by the adjustable section of the ends for supporting the back when in a lowered position.

2. In a bed-bed, the combination with a pair of ends, each composed of a stationary and an adjustable section hinged together whereby the said adjustable section may be extended in alignment with the stationary section and arranged at right angles to said stationary section, of a vertically-extending support arranged between the stationary section of the ends, an adjustable rest adapted to engage over and upon the top of said support when the said rest is in a lowered position, means for suitably hinging one side of the rest to the support to permit of elevating

the said rest, an adjustable back adapted to extend over and upon the top of the said support when the said back is in a lowered position, means for suitably hinging the back to the said support to permit of vertically adjusting the said back, an elongated clasp secured to the stationary section of the ends, clasp connected to the rest and engaging in the clasp of the ends for supporting the rest when in a lowered position, means carried by the adjustable section of the ends for supporting the back when in a lowered position, and means carried by the rear face of the back and adapted to extend over and engage the adjustable section of the ends when the latter are arranged at right angles to the stationary section for securing the back in a vertical position, substantially as herein shown and described.

3. In a bed-bed, the combination with a pair of ends each composed of a stationary and an adjustable section hinged together whereby the adjustable section may be extended in alignment with the stationary section, a support arranged between the sections, a rest, means for hinging the rest to the said support, an adjustable back, means for hinging the back to the support, means carried by the ends and engaging with the rest for supporting the same, means carried by the adjustable section for supporting the back when in a lowered position, and means carried by the rear face of the back and adapted to engage with the top of the adjustable section of the ends for securing the back in a vertical position.

700,043. **BOTTLE-STOPPER**. JOHN HANCOCK, Chesham, Canada. Filed Aug. 4, 1901. Serial No. 33,085. (No model.)

Claim.—1. The improved bottle-stopper comprising a body having a conical recess in its lower portion, the walls of the latter being tapered or beveled and the end of the same being flat as described, a conical plug conformed to and adapted to enter said recess and having an integral dash provided with a cap for operating it, an expansible ring or washer interposed between the flat end of the walls of the body and a shoulder of the plug, whereby upon rotating the cap the plug is drawn into the said recess and the ring or washer expanded as described.

2. In bottle-stoppers, a body-section provided with a conical recess in its bottom portion, a conical plug adapted to enter the said recess, an elastic band located at the exterior of the parts of the body and compressed by the action of the said plug when entering the recess in the body, a locking device connected with the plug, and a cap above the body of the stopper, the whole attached to the locking device, and through the medium of which cap the locking-bar is manipulated, as described.

3. A bottle-stopper, consisting of a body provided with a recess in its bottom, an expansible ring at the lower portion of said body, an expanding-plug which enters the recess in the body, the exterior portion of the plug being formed correspondingly to the inner contour of the said recess, a locking-bar connected with the plug, and a cap above the body, connected with the locking-bar and adapted in its operation to draw the plug upward in the said recess through the medium of the locking-bar, as set forth.

700,044. **APPARATUS FOR STRAINING WIRE**. THOMAS HUNT, Dunedin, New Zealand. Filed July 23, 1901. Serial No. 33,086. (No model.)

Claim.—In a wire-strainer, a longitudinally-extending main sliding bar having one end bent in a vertical manner terminating in a horizontally-extending arm with a grooved lower face, a pair of clips secured to said vertically-extending portion of the main bar, a movable head consisting of a vertical member having one side thereof formed with an offset provided with a grooved upper edge, a clip secured to said movable head above the said grooved offset, an auxiliary head mounted upon said main bar, a lever pivoted to the said auxiliary head and adapted to be re-depressed, and suitable connections between the lever and the movable head for causing the operation of the latter when the lever is re-depressed.

700,045. **BAKE-OVEN FOR GAS OR GASOLINE STOVE**. EDWARD W. HILLMAN, Kansas City, Kans. Filed Sept. 10, 1901. Serial No. 33,087. (No model.)

Claim.—1. In an oven of the character described, the combination with the casing provided with an inwardly-projecting annular flange having a central draft-opening, a deflector secured to said flange above said opening, and shelves in said opening and provided with supporting-legs, the supporting-legs of the uppermost shelf being longer than those of the lowermost shelf, the supporting-legs of said shelves extending laterally from the edges of said shelves and engaging the sides of the oven to prevent lateral shifting of said shelves, substantially as set forth.

2. In an oven of the character described, the combination with the oven-casing having a top consisting of two parts spaced apart, one of said parts being provided with draft-openings at the center and the other part being provided with draft-openings near its periphery, an inwardly-projecting annular flange secured to the lower end of the casing and having a central draft-opening, a deflector secured to said flange above said opening, and shelves in said opening and provided with supporting-legs, the supporting-legs of the uppermost shelf being longer than those of the lowermost shelf, the supporting-legs of said shelves extending laterally from the edges of said shelves and engaging the sides of the oven to prevent lateral shifting of said shelves, substantially as set forth.

700,046. **POWER SCREW-PRESS**. HENRY J. HARRIS, Toledo, Ohio. Filed Apr. 10, 1901. Serial No. 33,088. (No model.)

Claim.—1. In a press, the combination with a suitable frame and a reciprocating plunger mounted therein, of a screw-shaft for moving the said plunger, gearing for operating the said shaft, an actuating-shaft mounted upon the frame and adapted to engage oppositely-moving belts, sub-

leg-rods adapted to engage the said belt, rocking cam-blocks engaging the said shifting-rods, means for moving both the cam-blocks back and forth in opposite directions to each other simultaneously, comprising a bar connecting them, whereby the cam-blocks may be moved in either direction, or may be brought to a standstill, substantially as described.

2. In a press, the combination with a suitable frame, and a reciprocating plunger mounted therein, a curved shaft for moving the plunger, mechanism for connecting the said curved shaft with oppositely-moving power-belts, shifting-rods engaging the said belt, rocking cam-blocks engaging the said shifting-rods for reciprocating them, a bar connecting both the said cam-blocks together said bar being connected with means arranged in the path of a projection on the plunger, whereby the belt may be automatically moved to arrest the descent of the plunger and reverse its motion, said means also operating to automatically arrest its upward movement, substantially as described.

3. In a press, the combination with a suitable frame, and a reciprocating plunger mounted therein, a curved shaft for moving the plunger, mechanism for connecting the said curved shaft with oppositely-moving power-belts, shifting-rods engaging the said belt, cam-blocks engaging the said shifting-rods for reciprocating them, means connected with the said cam-blocks and arranged in the path of a projection on the plunger, whereby the belt may be automatically moved to arrest the descent of the plunger and reverse its motion, said means also operating to automatically arrest its upward movement, substantially as described.

4. In a press, the combination with a frame and a reciprocating plunger-carrier, of a shaft for driving said carrier, belt for actuating the shaft in different directions, shifting-rods engaging the said belt, pivoted cam-blocks, having cam-grooves formed in their faces, and adapted to engage wrist-pins on the said shifting-rods, rods connecting the said cam-blocks with each other and with a hand-lever, a rock-shaft mounted upon the frame of the machine and connected with the said rods, an actuating-arm on one end of the said rock-shaft, legs carried by the plunger and adapted to engage the said arm for automatically operating the belt-shifting mechanism to correspond with the position of the plunger in the machine, substantially as described.

5. In a press, the combination with a frame, a reciprocating plunger mounted therein, of shifting and gearing for operating the same, belt-shifting rods for controlling the application of power to the said mechanism, pivoted cam-blocks having cam-grooves upon their faces adapted to engage projections on the shifting-rods, the said cam-blocks being arranged to swing in opposite directions from each other, rods for operating them simultaneously, means for imparting movement to the rods from the plunger, the structure being such that when the plunger is at its lowest point one of the cams will be moved so as to rotate the shifting-rod and apply one belt so as to drive the machine in one direction, and when the plunger is moved in the other direction the other cam will be operated to produce an opposite movement of the parts, the structure also being arranged to bring the said mechanism to rest at the proper time, substantially as described.

6. In a press, the combination with a reciprocating plunger, of mechanism for moving the same up and down, cam-blocks for controlling the application of power to the said mechanism through the agency of belts, a rock-shaft for operating the said cam-blocks, an arm on the said rock-shaft, adjustable legs mounted on the said plunger, adapted to contact with said arm, belt for adjustably securing the said legs to the plunger, the said belt engaging a longitudinally-arranged groove upon the plunger, the structure being such that the legs may be so set that the plunger will be arrested in its downward movement and reversed at the proper time, and will be stopped in its upward movement at a proper point, substantially as described.

7. A press comprising a main frame, a reciprocating plunger mounted therein, a curved shaft for moving the same up and down, a bushing, having internal threads adapted to engage the threads upon the curved shaft, the said bushing being seated in a recess formed in the main frame, the said bushing having a head formed with beveled edges adapted to be brought opposite beveled faces on the main frame, and legs of a suitable size to fit between the beveled edges and the inclined faces by the insertion of which the bushing will be securely locked in position in the main frame, and means for reciprocating the carrier, substantially as described.

700,047. GRAIN-THRESHING MACHINE. FREDERICK H. HAYMAN, Grandfield, Iowa. Filed June 25, 1899. Serial No. 64,283. (No model.)

Claim.—A shaker suspended under the cylinder and concave, an extension at the rear of the said carrier adapted to serve as a bridge between the auxiliary shaker and the two parallel concaves and carrying drive-carriers, two endless carriers in parallel upwardly-inclined planes in rear of the auxiliary carrier on the shaker and means for simultaneously actuat-

ing the shaker and the endless carriers in contact with the cylinder, arranged and combined to operate in the manner set forth for the purpose stated.

700,048. HOO-CARDLER. HENRY E. HUGHES, Correspondent, Wm. Filed Jan. 7, 1899. Serial No. 64,284. (No model.)

Claim.—1. In a device of the class described the combination with a casing constructed to accommodate a lamp, a shelf hinged to said casing, a concave screen secured to said shelf and a reflector mounted to concentrate the light of said lamp on eggs placed on said screen, substantially as described.

2. In a device of the class described, the combination with a casing having diverging sides and divided into upper and lower compartments by a transverse partition, a hinged shelf located below an aperture communicating with said upper compartment, a concave screen secured to said shelf, and a reflector mounted to reflect the light of a lamp placed in said casing against eggs placed on said screen, substantially as described.

3. In a device of the class described, the combination with a casing having diverging sides and divided into upper and lower compartments by a transverse partition, a hinged shelf located just below an aperture in said upper compartment, a concave screen secured to said shelf and constructed to support eggs, means for adjusting said hinged shelf to vary the angle of incidence of light falling on the eggs placed thereon, and a reflector mounted to reflect the light of a lamp placed within said casing on eggs placed on said shelf, substantially as described.

700,049. FOLDING BOX. JAMES C. HAYMAN, Washington, D. C. Filed July 11, 1899. Serial No. 67,573. (No model.)

Claim.—1. In a pyramidal folding box, the combination with a bottom, of side walls hinged to the bottom and spaced from each other, said walls tapering toward their outer ends, side flaps hinged to the side edges of the walls and arranged to overlap when set up, and means carried by the flaps for detachably securing together the flaps which are on the corresponding edges of the side walls.

2. In a folding box, the combination with a bottom, of side walls hinged to the bottom and spaced from each other, said walls tapering toward their free ends, means for fastening the side walls together at their upper or free ends, side flaps hinged to the side edges of the walls, and interlocking means carried by the flaps for detachably securing together the flaps which are on the corresponding edges of the walls.

3. In a pyramidal folding box, the combination with a polygonal bottom, of side walls hinged to the opposite side edges of the bottom and tapering toward their free ends, means for securing the upper ends of the opposite side walls together, side flaps hinged to the side edges of the walls, said flaps being arranged in overlapping relation when the walls are set up, and means carried by the overlapping flaps for detachably securing them together.

4. In a pyramidal folding box, the combination with a polygonal bottom, of side walls hinged to the opposite side edges of the bottom, and tapering toward their free ends, side flaps hinged to the side edges of the walls, said flaps being arranged in overlapping relation when the walls are set up, one of the side flaps being provided with a flange extending to its hinged edge and the other having a tongue at its outer edge that engages in the slit, whereby the flaps may be detachably secured together.

5. In a pyramidal folding box, the combination with a bottom, of side walls hinged to the bottom and spaced from each other said walls tapering toward their outer ends, wings also hinged to the bottom between the side walls, said wings tapering toward their outer ends, flaps hinged to the side walls and adapted to be placed in overlapping relation over the wings when said side walls are set up, and detachably-interlocking means carried by the overlapping flaps for detachably securing them together.

6. In a pyramidal folding box, the combination with a rectangular bottom, of triangular side walls hinged to the opposite side edges of the bottom, wings hinged to the bottom between the side walls and tapering toward their outer ends, triangular flaps hinged to the side edges of the walls and being of the same size thereof, said flaps being adapted to be placed in overlapping relation over the wings when the walls are set up, one of the overlapping flaps having a tongue and the other a slit that receives the tongue whereby they are detachably secured together.

700,050. FLAT IRON. WILLIAM E. HUGHES, New York, N. Y. Filed Jan. 24, 1899. Serial No. 64,285. (No model.)

Claim.—1. A flat brush provided with a metallic band encircling the butt-end of the bristles, and having metallic outward extensions on the front and rear faces, linings of flexible material for the said extensions and extending beyond the outer ends of the extensions and beyond the sides thereof, and a connection between the front and rear metallic extensions at or near the sides thereof, as set forth.

2. A flat brush provided with a metallic band encircling the butt-end of the bristles and having outward extensions on the front and rear faces, linings of flexible material for the said extensions and extending beyond the ends, and a connection between the front and rear metallic extensions at or near their sides and comprising wires or cords extending around the outside of the bristles, as set forth.

3. A flat brush provided with a band encircling the butt-end of the bristles and secured on the head of the handle, the band having outward extensions on the front and rear faces, flexible linings for the said extensions and secured thereto by eyelets, and wires or cords extending through the eyelets at or near the sides of the extensions and connecting the front and rear extensions, as set forth.

4. A flat brush provided with a band encircling the butt-end of the bristles and secured on the head of the handle, fastening devices extending through the band and bristles and engaging the wooden core in the butt-end of the bristles, the said band having outward extensions on the front and rear faces, flexible linings for the said extensions extending beyond the outer ends of the extensions, and the sides thereof and wires or cords connecting the front and rear extensions at or near the sides thereof, as set forth.

700,051. BERRY FOR UNLOADING SHIPS. WILLIAM E. HUGHES, Louisville, Ky. Filed Sept. 12, 1899. Serial No. 73,142. (No model.)

Claim.—1. In boats for unloading ships, the combination of a trolley-wagon J, an inclined trolley-track A attached to the deck of the ship by a hinge and pivot, and supported from above by guys; said trolley-track being a single beam of "I-beam" section, with the wheels of the trolley-wagon running on and outside of the bottom flange thereof, together with line K attached to a hook M, running through said trolley-

wagon and along said trolley-track; said line being controlled by engine, all for the purpose of lifting freight out of the ship's hold toward the outward end of the trolley-track, in order to transfer it to a deck or to another ship, substantially as described.

2. In boats for unloading ships, the combination of a trolley-wagon J on inclined trolley-track A attached to the deck of a ship by a hinge and pivot, and supported from above by guys, together with line K attached to a hook M, running through said trolley-wagon and along said trolley-track; said line to be controlled by engine, all for the purpose of lifting freight out of the ship's hold toward the outward end of the trolley-track, in order to transfer it to a deck or to another ship, substantially as described.

700,052. ELECTRIC MOTOR-CAR OR LOCOMOTIVE. CHAS. H. KAMM, Budapest, Austria-Hungary. Filed Apr. 12, 1899. Serial No. 64,286. (No model.)

Claim.—1. An electric motor-car or electric locomotive for high-tension electric system, having the conductors, motors and all parts con-

rying current within the car insulated by but insulated from metallic covers surrounding and protecting all such insulated parts, such metallic covers not being part of the electric circuit, but means being provided to electrically connect said covers to the rails, substantially as and for the purpose described.

2. An electric motor-car or electric locomotive for high-tension systems, having the current-carrying parts insulated within but insulated from protective metallic covers electrically connected to the wheels of the vehicle, to form an earth connection for the said covers, as and for the purpose described.

700,058. KNIFE FOR GULLOTINE PAPER-CUTTING MACHINE. THOMAS R. KIMMEL, London, England. Filed Mar. 7, 1898. Serial No. 97,112. (No model.)

Claim.—1. A knife for guillotine paper-cutting machines, provided with a hole for the passage of a bolt therethrough, and a recess concentric to said hole, of a hole having a chamfer adapted to extend through said hole in the knife, and having its head provided with eccentric portions to engage said recess in the knife, whereby said knife may be adjusted by turning said bolt, substantially as described.

2. The combination with a knife for guillotine cutting-machines, provided at intervals with a pair of apertures arranged in a line substantially perpendicular to the edge of the blade, and a series of bolts, each having a chamfer adapted to pass through one of said pair of apertures, and having its head provided with an eccentric projection adapted to pass through the other aperture of a pair, whereby said knife may be adjusted by removing said bolts and reversing them, substantially as described.

3. In a guillotine cutting-machine, the combination with the knife-carriage provided with a bolt-hole formed therein, of the knife provided on one face with a recess, and having two holes formed in the knife at the bottom of said recess, said holes being in a line substantially perpendicular to the cutting edge, of a securing and adjusting bolt having a chamfer adapted to pass through one of the holes in said knife, and the hole in the knife-carriage, said bolt having a head adapted to fit in said recess of the knife and provided with a projection to engage the other of said holes, substantially as described.

4. A knife for guillotine paper-cutting machines having a number of recesses formed at its top or back, the said recesses being provided with two holes through the knife, substantially as, and for the purpose, hereinafter described.

700,054. FOLDING IRONING-TABLE. WILHELM R. KRAFT, Grand Rapids, Mich. Filed June 17, 1891. Serial No. 64,995. (No model.)

Claim.—1. In an ironing-table, a top, a plurality of standards pivoted to each other and one of them pivoted to the top, a part fastened to said top, having grooves, projections upon one of the standards slotted in said grooves, and a ratchet-frame hinged to the top, the notches of which are adapted to engage one of the standards, and having projections at each side thereof extending outwardly therefrom, the standard being recessed to receive said projections.

2. In combination with a table-top, a pair of front standards pivoted thereto, a pair of rear standards pivoted to said front standards, a bed-frame secured to the table-top and provided with a rod connecting its free ends and extending on either side beyond said frame, a ratchet-rod connecting the upper ends of the rear standards, having its ends extending on either side beyond the standards and adapted to engage with the grooves in the bed-frame, substantially as described.

3. In an ironing-table a top, a bed-plate on the under side of said top near one end thereof, a bed-frame on the under side of the top at the

opposite end of the latter, means for reversibly connecting the top to the bed-plate and bed-frame, a standard having projections at one end and the bed-frame being grooved to receive said projections, a second standard pivoted to the other standard and hinged to said bed-plate, a ratchet pivoted to the frame, said ratchet serving to engage the first standard, and means carried by the ratchet for preventing said projections from being displaced from their grooves.

4. In an ironing-table the combination of front and rear standards a bed-frame K having grooved side pieces and a ratchet-frame J hinged to the said bed-frame, a rod I connecting the upper ends of standards E and extending on either side into the grooves in side pieces of bed-frame K, hooked notches H in hinged ratchet-frame adapted to engage ratchet-rod I, a rod O connecting the free ends of the ratchet-frame and extending beyond on each side, and projects P on the inside of standards K, all substantially as and for the purpose set forth.

700,055. MACHINE FOR SEPARATING AND CLEANING CORN CULLINGS. RICHARD S. KRAFT, Toledo, Kans. Filed Jan. 11, 1899. Serial No. 42,912. (No model.)

Claim.—1. The combination, in a machine for separating and cleaning corn cullings, of an inclined cylindrical rotating screen, its upper portion being of a fine mesh, and its lower portion of a coarse mesh; a cylindrical rotating screen of larger diameter and substantially the same size mesh as said upper portion, and surrounding, parallel to and concentric with, said lower portion, the lower end of said larger screen being flanged outwardly; and an annular or ring-like conveyor-box, which induces the said flanged lower end of said surrounding screen, substantially as shown.

2. In a machine for separating and cleaning corn cullings, the combination of a rotating cylindrical screen and a wind-distributing box, said box being placed along and near, but not in contact with, the outside of said screen, and consisting of an elongated box, its inner face open, containing a series of graduated vanes or wind-guides, fixedly attached within said box, at an angle to the direction of the incoming blast, thence toward said screen, substantially as shown.

3. The combination, in a machine for separating and cleaning corn cullings, of a primary inclined cylindrical rotating screen of a large mesh; a secondary inclined cylindrical rotating screen having its upper portion fine-meshed and its lower portion coarse-meshed; a tertiary inclined cylindrical rotating screen, of a fine mesh, surrounding, parallel to and concentric with, the lower, or coarse-meshed portion of said secondary screen, and having its lower end flanged outwardly; an annular ring-like conveyor-box, which has an annular opening in its inner facing side, in which is rotatably located said flanged end of said tertiary screen; an inclined representing shaker-screen, and an incline plane located facing the lower end of said shaker-screen, and a blower with a throat or guiding-opening, which direct the blast from the blower along substantially horizontally under said shaker-screen and against said incline plane; together with suitable chutes and receptacles, substantially as shown.

700,056. APPARATUS FOR THE KNOWING OF FATS ON THE LIVER. GUNTER KRIEGER, Wiesbaden, Germany. Filed Aug. 26, 1894. Serial No. 73,265. (No model.)

Claim.—1. In an apparatus for separating fat from liquids, the combination of an outer vessel, an inner vessel therein open at bottom, an overflow for the outer vessel below the top of the inner vessel, and an inlet-pipe leading laterally through the walls of both vessels and opening into the inner vessel below the water-level, substantially as described.

2. In an apparatus for separating fat from liquids, the combination of an outer vessel, an overflow-channel at the upper end thereof, a cylindrical open-ended vessel within the outer vessel, but separated from the walls thereof and rising above the overflow-channel, an inlet-pipe

opening into the inner vessel below the water-level therein, and an overflow-pipe from said channel, substantially as described.

3. In an apparatus for separating fat from liquids, the combination of the outer vessel having an annular overflow-channel around its top, and an overflow-pipe from said channel, a cylindrical vessel located within the outer vessel open at bottom and extending above the outer vessel, and an inlet-pipe arranged below the channel and passing laterally through both vessels and opening upwardly into the inner vessel below the water-level thereof, substantially as and for the purpose described.

700,057. BROOM-CORNER-KNIFE. BRUNO P. LA GRAM, A-Ges, Conn. Filed Feb. 15, 1891. Serial No. 67,069. (No model.)

Claim.—A downwardly tapering detachable broom-corner-knife having one longitudinal portion of iron, and the other portion of steel, the steel being harder in its exposed parts remote from the iron.

700,058. BROOM-CORNER-KNIFE. GUNRAY A. LAMSON and JOHN E. JOHNSON, Worcester, Mass. Filed June 2, 1893. Serial No. 10,945. (No model.)

Claim.—1. In a knife of the kind described, the combination of a blade having its sides converge toward the rear edge, and having its front edge sharpened, a handle-retaining member held upon the rear of the blade and U-shaped handle-sections carried by the said retaining-section, substantially as shown and described.

2. In a knife of the kind described, the combination of a blade having a handle-retaining member connected thereto, and handle-sections slidably held by said retaining member, substantially as shown and described.

3. In a knife of the kind described, the combination of a blade having one edge provided with a cutting-surface, a handle-retaining member arranged on said blade opposite the cutting-surface, the said retaining member having its free edges bent to form guides, and handle-sections having their outer ends provided with apertures, their inner ends arranged to fit and slide within the guides of the retaining member, and a cord or strap connecting the same ends of the handle, substantially as shown and described.

700,059. CALIBREBAR. MALVIN LAMSTER, New York, N. Y. Filed Nov. 27, 1891. Serial No. 38,929. (No model.)

Claim.—1. A display device of the class described, comprising a plate having a pair of parallel slots, and a display-strip for engagement

with the slots and extending at its ends through the slots to display a portion of the strip at the front of the plate between the slots, said display-strip being flexible and having its ends free and curled up at the back of the plate adjacent to the slots to hold the strip in position, as set forth.

2. A display device of the class described, comprising a plate having a pair of parallel slots, and a display-strip for engagement with the slots and extending at its ends through the slots to display a portion of the strip at the front of the plate between the slots, said display-strip being flexible and having its ends free and curled up at the back of the plate adjacent to the slots, the curled free ends extending toward each other to exert pressure in opposite directions on the displayed portion, to draw the same taut on the front face of the plate, as set forth.

3. A display device of the class described, comprising a plate having pairs of parallel slots, the pairs standing at angles to each other, and a display-strip for each pair of slots, extending at its ends through the slots to display a portion of the strip at the front of the plate between the slots, each of the display-strips being flexible and having its ends free and curled up at the back of the plate adjacent to the slots, the curled free ends extending toward each other to exert pressure in opposite directions on the displayed portion, to draw the same taut on the face of the plate, as set forth.

4. A display device of the class described, comprising a flat body having a pair of spaced and parallel slots, and a display-strip passed through the slots to display a portion of the strip at the front of the body between the slots, the said strip being of resilient material and held in the position to which it is adjusted by its resiliency, as set forth.

700,060. BOOK-SHELF AND SHIPPING-CRATE. ALVA A. LUDLOW, Dayton, Ohio. Filed May 7, 1891. Serial No. 34,173. (No model.)

Claim.—1. In a bookcase and shipping-box, a body portion adapted to be used as a book case or shelf, said body portion being of a depth sufficient to provide a space between the top of the books and the bottom of the contiguous book case or shelf, to permit the books being tilted, straps secured to the body portion, and provided with slots, a cover consisting of sides, a front, and a back, books secured to the front and adapted to engage the slots, and means for securing the sides to the body portion.

2. In a bookcase and shipping-box, comprising a body portion adapted to be used as a book case or shelf, said body portion being of a depth sufficient to provide a space between the top of the books and the bottom of the contiguous book case or shelf, to permit the books being tilted, and a cover adapted to be secured to said body portion, to embrace the edges and sides of the body portion to protect them from injury.

3. The combination with a body portion; of a cover consisting of sides having top and front flanges provided with perforations, of a front having perforations, and of a top having perforations, plates having perforations, and secured to said top and front, threaded screws mounted in the perforations in the front and top, screw-bolts passing through the perforations in said plates into said screws to secure them to the plates, screw-bolts passing through the perforations in the flanges into said screws to secure the front, top and sides together, and means substantially as described for securing the cover to the body portion.

4. A shipping-box comprising a body portion having recesses in the back thereof and passages communicating with said recesses and the edges and sides of said body, L-shaped straps secured to said body portion and having perforated ends fitting in said recesses in said body, and the opposite ends of said straps are provided with slots, a cover provided with perforations adapted to slide with said passages, bolts upon said cover to engage said slots, and screw-bolts passing through said perforations and passages into said recesses, substantially as described.

5. In a bookcase and shipping-box, comprising a body portion adapted to be used as a book case or shelf, and consisting of a bottom, sides and a back, said body portion being of a depth sufficient to provide a space between the top of the books and the bottom of the contiguous book case or shelf, to permit the books being tilted, and a cover adapted to be secured to said body portion and consisting of a top to occupy said space to prevent the books having any movement in the box, a front and sides to embrace the edges and sides of the body portion to protect them from injury.

1. In a bookcase and shipping-box, a body portion adapted to be used as a book case or shelf, said body portion being of a depth sufficient to provide a space between the top of the books and the bottom of the contiguous book case or shelf, to permit the books being tilted, straps secured to the body portion and provided with slots, a cover consisting of sides having top and front flanges, a front end and a back, means for securing the front and back to the flanges, books secured to the front and adapted to engage the slots, and means for securing the sides to the body portion.

700,061. SEATE. THOMAS E. LUMA, Minneapolis, Minn. Filed Jan. 2, 1891. Serial No. 82,888. (No model.)

Claim.—1. The grate herein described comprising the main or basket section having a bottom frame provided with cross-bars spaced apart and with side bars inclining inwardly toward the bottom frame, a depending pivot-rod on the bottom frame, and the shaker having a handle and a frame and cross-bars adapted to partly close the space between the bars of the bottom of the main section and a bearing opening or slot for the pivot-rod elongated from front to rear whereby the shaker-section can be oscillated with respect to a vertical axis and reciprocated, substantially as set forth.

2. The combination of the main or basket section provided with side bars and with the flat bottom having cross-bars, and the shaker-section supported below said bottom and capable of oscillating with respect to a vertical axis and reciprocating substantially as set forth.

3. The grate herein described having the main section provided with a bottom having openings, and the shaker-section supported to oscillate with respect to a vertical axis and to reciprocate beneath said bottom substantially as set forth.

4. The combination of the grate-section having a depressed or basket form, and the shaker arranged close beneath the grate-section and capable of oscillating with respect to a vertical axis and of reciprocating substantially as set forth.

5. The combination of a fixed or main grate-section having a depressed or basket form and a movable shaker close beneath said section and capable of oscillating with respect to a vertical axis and of reciprocating substantially as set forth.

6. A grate comprising the main section having its bottom formed of cross-bars spaced apart, and the shaker-section supported close below the said bottom and having its cross-bars formed to partly close the space between those of the grate-bottom, each shaker being capable of oscillating with respect to a vertical axis and of reciprocating substantially as set forth.

7. A grate composed of a main fixed section and a shaker-section below the fixed section, the entire shaker-section being arranged and supported to oscillate with respect to a vertical axis and to reciprocate beneath the fixed section substantially as set forth.

8. The combination of the fixed section having a stud and a shaker-section having an elongated opening or slot receiving the stud, whereby the shaker-section can be oscillated with respect to a vertical axis and reciprocated, substantially as set forth.

9. The grate herein described, comprising the basket-section having its bottom formed with cross-bars, and provided on said bottom with a depending pivot-rod, and a shaker comprising a frame and cross-bars, and provided with a vertical opening for the passage of the end of the basket-frame, said opening being elongated whereby the shaker-section can be oscillated around the pivot-rod as a vertical axis, and can be reciprocated below the basket-section substantially as set forth.

700,062. MANOLE. DAVID LINDAHL, West Ny City, N.Y. Filed Nov. 2, 1891. Serial No. 81,088. (No model.)

Claim.—In a manhole, the combination with the side standards, each of which consists of parallel upright bars, the lower ends of the bars of each standard being rounded from a point midway their length to their upper ends to form grooves or ways, filling-blocks clamped between said bars at their lower ends, blocks mounted to slide in said grooves or ways,

a roll journaled in bearings formed between the contiguous faces of the filling-blocks, a roll journaled in bearings formed in the contiguous faces of the sliding blocks and the upper faces of the uppermost filling-blocks, and means for exerting a downward pressure upon said sliding blocks, substantially as set forth.

700,063. PROCESS OF RECONSTRUCTING RAILROAD-RAILS. VERNON T. LYMAN, Chicago, Ill. Filed Jan. 4, 1892. Serial No. 83,542. (No model.)

Claim.—1. The process of transforming flanged rails into grooved rails while in position on the road-bed, which consists first in swinging or offsetting the edge of the flange of the rail, and then cutting a strip of metal on the flange parallel to the ball or tread of the rail.

2. The process of transforming flanged rails into grooved rails, while in position on the road-bed, which consists in first swinging or offsetting the edge of the flange of the rail at one or more parts to form projecting portions at said edge, second, protecting the portion of the flange adjacent to the tread, third, running a mass of molten metal along the unprotected outer portion of the flange and parallel to the ball or tread of the rail, and allowing the metal to harden on the flange, thereby forming a second tread spaced from the tread of the rail to produce the groove, the swung or offset portion of the flange serving to retain the second tread in position.

700,064. UPRIGHT-ROCKING. ARTHUR J. MANTON, N.Y. Filed Feb. 3, 1892. Serial No. 82,311. (No model.)

Claim.—1. The combination in a steam-engine, of the cylinder, valve-chests arranged on opposite sides of the same, there being ports or passages leading from the opposite ends of the cylinder to said valve-chests, slide-valves disposed within the chest, valve-rods connected to said

valve and to each other, one of said valve-rods having a pair of lugs, and a tappet-bar actuated by the movement of the piston of the engine and adapted to make contact with said lugs.

2. The combination in an engine, of the cylinder, valve-chests arranged on opposite sides of the same, there being ports or passages leading between the valve-chests and the opposite ends of the cylinder, a piston in said cylinder, a piston-rod connected to the piston, a tappet-bar connected to and movable with the piston-rod, valve-rods connected to the valves, a pivoted lever to which both rods are connected, and one of said valve-rods being provided with lugs adapted to be engaged by the tappet-bar, substantially as specified.

3. The combination in a steam-engine, of the cylinder, valve-chests arranged on opposite sides of the same, there being ports or passages leading between the valve-chests and the opposite ends of the cylinder, a piston in said cylinder, a piston-rod 7 connected to the piston, a cross-head 25 connected to the piston-rod, cross-head guides 24 carrying said cross-head, a tappet-bar 20 connected to the cross-head and projecting laterally therefrom, a transverse bar 26 connecting the cross-head guides, a bar 27 pivotedly connected to said bar 26, an adjustable valve-rod 22 connecting the exhaust-valve to one end of the bar 27, an adjustable valve-rod 18 connecting the steam-valve to said bar 27, lugs 31 carried by said valve-rod 18, and a tappet-bar 29 carried by said lugs and adapted for contact with said tappet-bar 29, substantially as and for the purposes specified.

700,065. SHOE-GRADING DEVICE. HENRIK HANSEN, Copenhagen, Denmark. Filed Dec. 14, 1891. Serial No. 82,888. (No model.)

Claim.—1. In a device of the character described, the combination with toe and heel pieces, said toe-piece comprising oppositely-arranged sections, of springs 5 arranged between the said sections, pins 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.

3. In a device of the character described, the combination with toe and heel pieces and a rod a pivotally connected at one end with the toe-piece, of a vertically-movable slide carried by the heel-piece and provided with inclined slots, a fixed guide-piece carried by the heel-piece and provided with horizontal slots, and a pin upon which the other end of the rod is mounted and passing through the slots in the slide and guide-piece, and means for operating the slide.

4. In a device of the character described, the combination with toe and heel pieces, said toe-piece comprising oppositely-arranged sections having a yielding connection to adapt said sections for lateral movement relatively to each other, of plates 4 carried by the sections of the toe-piece and provided with eyes, a pin or bolt seated within the eyes, a rod mounted at one end upon the said pin or bolt, and springs mounted upon the bolt at each side of the rod, the said rod having a pivotal and slidable connection with the heel-piece, as and for the purposes specified.

700,066. SHOE-GRADING. HENRIK HANSEN, Copenhagen, Denmark. Filed Dec. 14, 1891. Serial No. 82,888. (No model.)

Claim.—1. A shoe-grading device having inclined water-tubes, front and rear headers to which said tubes are connected, and water and steam drums arranged transversely above said tubes, one of said drums being situated directly over a series of heating-tubes having communication between the front and rear headers, substantially as described.

2. The combination in a boiler, of a series of inclined heating-tubes, front and rear headers to which said tubes are connected, with transverse

drums mounted above said tubes, said drums being connected together and to the front and rear headers, the connections between said drums affording a means of circulation through the same, substantially as described.

3. The combination in a steam-boiler, of inclined heating-tubes, front and rear headers to which said tubes are connected, two transverse heating-drums mounted above said tubes, said drums being connected together by horizontal pipes providing a circulation between the same, one of said drums being connected to the front header, and a series of tubes coupling the other drum to the rear header, said tubes extending across the opening leading to the stack, substantially as described.

4. The combination of inclined heating-tubes, front and rear headers, two transverse drums, one mounted above the front header and connected thereto, the other mounted above the heating-tubes, a series of circulating-tubes connecting said drum with the rear header, the two drums being connected at top and bottom, substantially as described.

5. The combination of the vertically-arranged polygonal front and rear headers, inclined heating-tubes coupled to the two sets of headers, and drums mounted above said heating-tubes and connected together by pipes affording a circulation between the same, said drums being also connected to the front and rear headers, substantially as described.

6. The combination of the front and rear headers, inclined heating-tubes coupled therein, drums connected to the upper portion of the headers, a collection-chamber mounted in front of the fire-box directly below the front header and coupled thereto, with independent circulating-pipes extending from both ends of said collection-chamber to one of the drums exterior of the boiler, substantially as described.

7. The combination of a casing, a collection-chamber supported thereby and extending through the side walls thereof, a series of vertically-arranged headers, each header being coupled to the collection-chamber, inclined heating-tubes coupled to the front header, rear header to which the heating-tubes are also connected, a drum mounted above the front header, and pipes coupling the front header to the drum, said drum being connected to the rear header, substantially as described.

8. The combination of a front header made up of two series of sections arranged vertically, a transverse section to which both series of vertically-arranged sections are coupled, a rear header, and heating-tubes connected to the front and rear headers, substantially as described.

9. The combination of front and rear headers and inclined heating-tubes, said front header being made up of two series of vertically-arranged sections and a said cross-section coupled to the vertical sections, the heating-tubes coupled to the vertical sections arranged one above another, while the heating-tubes coupled to the cross-section are arranged in line with the space between the other heating-tubes, substantially as and for the purposes set forth.

10. The combination of the front and rear headers, inclined heating-tubes coupled therein, said front header made up of sections spaced apart

so that access may be had to the combustion-chamber to clean the tubes, and removable non-combustible sections of filling material for closing the space between said headers, substantially as described.

11. The combination of front and rear headers, inclined heating-tubes coupled thereto, the front header made up of sections spaced so that access may be had to the combustion-chamber to clean the tubes, with asbestos plates adapted to said openings, substantially as described.

12. The combination with a front header made up of a series of vertically-arranged sections, of a rear header made up of vertically-arranged sections, heating-tubes situated one above another and coupled to the sections of the front and rear headers, a horizontal section connected to the upper end of the rear header-sections, circulating-tubes coupled to the said sections, two drums coupled together, one of said drums connected to the circulating-tubes and the other connected to the front header, substantially as described.

13. The combination of a fire-chamber, an inclined back wall, a rear header mounted above the back wall and inclined forward, inclined heating-tubes coupled to the back header, a front header coupled to the heating-tubes, a sediment-chamber under the front header at the front of the fire-chamber, two drums, one mounted above the front header and coupled thereto and the other mounted above the heating-tubes and connected at top and bottom with the other drum, the outlet-flow to the steam from the combustion-chamber being between the said last-mentioned drum and the rear header, and a series of circulating-tubes coupling the rear header to the drum and extending across the fire to the stack, substantially as described.

14. The combination in a steam-boiler furnace, of the front header, heating-tubes, rear header made up of a series of vertical sections closed at their bottom, said sections being coupled together at the side near the base by nipples, a drum, and circulating-pipes connecting the drum with the front and rear headers, substantially as described.

700,067. CHAIR. JAMES F. MOORE, Fairland, Md. Dec. 2nd. Filed May 20, 1901. Serial No. 61,912. (No model.)

Claim.—1. The combination with a chair-bottom and a back hinged thereto; of a lever rigidly connected to the back, a plunger pivotally connected to the lever and located beneath the chair-bottom, a spring for forcing the plunger backward, and means whereby the plunger is permitted to move in one direction but not in the other.

2. The combination with a chair-bottom and a back hinged thereto; of a lever rigidly connected to the back, a plunger pivotally connected to the lever and located beneath the chair-bottom, a plunger-tube secured to the chair-bottom, an extension to the plunger slidably mounted in the tube, a spring for forcing the plunger and its extension in one direction, a pivoted latch normally projecting into the tube, and means whereby said latch permits the plunger to move in one direction but not in the other.

3. The combination with a chair-bottom and a back hinged thereto; of a lever rigidly connected to the back, a plunger pivotally connected to the lever and located beneath the chair-bottom, a plunger-tube secured to the chair-bottom, an extension to the plunger slidably mounted in the tube, a spring for forcing the plunger and its extension in one direction, a pivoted latch normally projecting into the tube, a spring-controlled latch operating and releasing said latch extending to the edge of the chair-seat, and means whereby the latch permits the plunger to move in one direction but not in the other.

700,068. FEED-WATER CLEANER. DONALD R. MORRIS, Hartlepool, England. Filed June 10, 1901. Serial No. 61,916. (No model.)

Claim.—1. In a feed-water cleaner, a suitable chamber, heater-coils therein, a discharge-pipe extending through the center of said coils, a flaring mouthpiece on said pipe to form a restricted passage between it and the walls of the chamber, and a contracted top on the heater for collecting oil and air separated from the water, means for discharging the oil and means for automatically discharging air, substantially as and for the purpose set forth.

2. In a feed-water cleaner, a suitable chamber, having a contracted top, means for heating the water, a float-chamber communicating with the first-mentioned chamber below the water-level and with the air-space formed in the contracted top, an open-ended float in the float-chamber, a valve controlling an air-outlet operated by the float, substantially as and for the purpose set forth.

3. In a feed-water cleaner, a suitable chamber having a conical top, means for heating the water therein, a float-chamber, an open-ended float therein, a pipe connecting the lower end of the float-chamber with the first-mentioned chamber below the normal water-level and projecting into the end of said float, a pipe connecting the open end of the conical top of the first-mentioned chamber with the upper part of the float-chamber, an air-outlet for the float-chamber, a valve carried by the float controlling the air-outlet, means for drawing off the oil and means for visibly indicating the flow of air from the float-chamber, substantially as and for the purpose set forth.

4. In a feed-water cleaner, a suitable chamber having a conical top, means in the chamber for heating the feed-water, a float-chamber, an open-ended float therein, a pipe connecting the lower end of the float-chamber to the first-mentioned chamber below normal water-level, and projecting into the open end of the float, a pipe connecting the open end of the conical top with the upper end of the float-chamber, stop-cocks in each of said pipes whereby the float-chamber can be cut off from the first-mentioned one and the float proportionally loaded to its working pressure in the first-mentioned chamber, an air-outlet a needle-valve carried by the float controlling the air-outlet, and a revolving vane over the air-outlet to visibly indicate a current of air from the float-chamber, substantially as and for the purpose set forth.

5. In a feed-water cleaner, a suitable heating-chamber having a conical top, a float-chamber communicating with the heating-chamber below water-level therein and with the air-space in the conical top, a float in said chamber, a valve controlling air-outlet operated by the float and an air-outlet in the conical top, substantially as and for the purpose set forth.

6. In a feed-water cleaner, a suitable heating-chamber having a conical top, a float-chamber a pipe connecting the latter with the heating-chamber below normal water-level therein and one connecting its upper end with the conical top, an open-ended float in said chamber, the first-mentioned pipe entering the open end of the float, a needle-valve connected to the float and controlling an air-outlet, a vane adapted to be moved by the current of air having from said air-outlet, a water-level indicator connected to the float and means for withdrawing oil from the surface of the water in the conical top, and means within the chamber for throttling the feed-water near the top of the chamber, substantially as and for the purpose set forth.

700,069. GROSS-JUSTICE. WILLIAM G. HILLMAN, Pasadena, Cal. Filed Sept. 14, 1901. Serial No. 71,421. (No model.)

Claim.—1. In a shoe-duster, the combination with a treadle, of an auxiliary shaft arranged above the treadle, an operative connection between the treadle and shaft for imparting motion to the latter, and one or more brushes or dusters connected with said shaft and adapted to be thrown into contact with the shoe while the foot is resting on the treadle.

2. In a shoe-duster, the combination with a suitable base, and a frame extending upward therefrom, of a treadle mounted on the base, an auxiliary shaft journaled in the frame, a flexible connection between the treadle and shaft, a spring for retracting or reversing the direction of rotation of the shaft, and an auxiliary hand on said shaft provided with one or more dusting-brushes.

700,070. BOTTLE FOR PREVENTING REFILLING. JAMES F. MCGRAW and General G. DUNNAN, Wellington, New Zealand. Filed Oct. 1, 1901. Serial No. 71,399. (No model.)

Claim.—1. In a bottle to prevent refilling a ball resting on an internally-projecting annular seat in the bottle-neck in combination with a guard secured in the bottle-neck above the ball comprising a lower insert or perforated diaphragm, an intermediate insert or perforated diaphragm having above and below it a supporting-plate, and an upper diaphragm all as and for the purposes hereinafter described and as illustrated in the drawings.

2. An improvement in bottles to prevent refilling consisting of a bottle having a body the neck of which is ground or fruted and latched and near the bottom of which is an annular protruding seat in combination with a ball resting on said seat, a guard secured in the bottle-neck, above the ball, comprising a lower insert or perforated diaphragm, an intermediate insert or perforated diaphragm having above and below it supporting-plates and an upper insert or perforated diaphragm, said diaphragms being arranged as described all as and for the purposes hereinafter described, and as illustrated in the drawings.

700,071. PENCIL-SHARPENER. EDWARD L. McVITT, Detroit, Mich. Filed Dec. 2, 1901. Serial No. 64,066. (No model.)

Claim.—1. A pencil-sharpener comprising a sheet-metal plate provided with a lengthwise opening and a perforated and bent substantially at right angles to the face of the plate and a bridge with a peripheral opening located across the opening in the plate.

2. A pencil-sharpener comprising a sheet-metal plate provided with a lengthwise opening, a bridge with a peripheral opening located across

the opening in the plate having a portion of the lengthwise opening each side of the bridge, and a spring secured to the back of the plate.

3. A pencil-sharpener comprising a plate with a lengthwise opening and an end provided with an opening, a bridge located across the lengthwise opening and having a conical recess and a peripheral opening.

4. A pencil-sharpener comprising a sheet-metal plate provided with a lengthwise opening, a bridge with a peripheral opening located across the opening in the plate and a plate-spring secured to the back of the plate and held in place by the bridge.

5. A pencil-sharpener comprising a sheet-metal plate provided with a lengthwise opening, a bridge with a peripheral opening located across the opening in the plate, and a plate-spring with a lengthwise opening secured to the back of the plate and held in place by the bridge.

700,072. WEIGHING-MACHINE. EDWARD L. McVITT, St. Paul, Minn. Filed May 17, 1901. Serial No. 69,971. (No model.)

Claim.—1. The herein-described apparatus for weighing articles in bulk, comprising a supporting-structure, a receptacle for the articles to be weighed, pivotally attached to said framework, said pivotal supports including links pivoted at their upper ends to said framework and pivotally connected at their lower ends to the receptacle, said supports or receptacles being arranged entirely below the upper pivots of the links, and restraining means for holding said support or receptacle in a position to one side of the position which it would naturally assume under the action of gravity, against which means said receptacle exerts force in a horizontal line and means for measuring said horizontal pressure or force and indicating therefrom the weight placed on the receptacle.

2. The herein-described apparatus for weighing articles in bulk, comprising a framework, two pairs of depending arms or links pivoted at their upper ends to said framework, a support or receptacle for the article to be weighed in which the lower ends of said arms are pivotally connected, said support or receptacle being arranged within the framework, and centrally below the upper pivots of the links, said receptacle having an inclined bottom with a discharge at the lower end thereof, substantially as described.

3. An apparatus for weighing articles in bulk, comprising a supporting-structure, links pivotally hung from said supporting-structure, a receptacle supported entirely below the upper pivotal connections of the links and pivotally attached at the lower ends of said links, said receptacle

ole being substantially triangular in shape with a bottom inclined downwardly and having a discharge-opening at the lower end, brass-rods extending from the lower end of one pair of links and secured to the receptacle at a point adjacent its discharge-opening, and restraining means arranged in line with the pivot-points of the links; substantially as described.

700,078. FIRE-SCAPES AND FIRE-ALARM FOLDING LADDER. RICHARD HENRIKSEN, Auckland, New Zealand. Filed Oct. 1, 1904. Serial No. 77,282. (No model.)

Claim.—1. In a ladder, side pieces having bearings, rungs or steps the ends of which extend through said bearings and are oppositely turned to embrace said bearings, combined with a catch for holding said side pieces together when folded up, and a pivoted ladder for one of said side pieces connected with the catch.

2. In a ladder, side pieces having bearings, rungs or steps the ends of which extend through said bearings and are oppositely turned to embrace said bearings, combined with a catch for holding said side pieces together when folded up, a pivoted ladder for one of said side pieces connected with the catch, and means carried by one of said rungs for operating a signal.

700,074. WIRE FENCE. FRANKLIN W. ORIN and JOHN G. ORIN, Ireland, Ind., assignors of one-third to HENRY WINDGATER, Ireland, Ind. Filed Nov. 20, 1901. Serial No. 23,600. (No model.)

Claim.—1. In a fence, the combination of a post, a fence-wire supported thereby, at two points, and a brace connected to the said fence-wire, between said supported points thereof, said wire and brace each maintaining the tension of the other, and whereby the sagging of the wire between two posts adds tension to the brace, substantially as described.

2. In a fence, the combination of a post, a fence-wire supported thereby at two points, a brace for the post, and an adjustable connection between the said brace and the said wire, said connection being attached to the wire between the supported points thereof, said wire and brace each maintaining the tension of the other, substantially as described.

3. In a fence, the combination of a post having a transverse slot, a fence-wire supported by the post, a brace having a hight disposed in the said slot, the said brace being connected to and supported by the said wire substantially as described.

4. In a fence, the combination of a base, a post supported on and detachable from the base, a fence-wire supported by the post at two points, and a brace-wire transversely disposed with reference to the post, the hight of said brace-wire being connected to said fence-wire between the supported points thereof, said brace-wire contributing to the tension of said fence-wire, substantially as described.

5. In a fence, the combination of a base, a post supported on and detachable from the base, a wire fabric having its upper and lower wires engaged with the upper and lower ends of the post and its intermediate wires bearing against one side of the post, and a brace for the latter, substantially as described.

6. In a fence, the combination of a base, a post supported on and detachable from the base, a wire fabric having its upper and lower wires engaged with the upper and lower ends of the post and its intermediate wires bearing against one side of the post, and a brace for and detachable from the latter, substantially as described.

7. In a fence, the combination of a base, a post supported on and detachable from the base, a wire fabric having its upper and lower wires engaged with the upper and lower ends of the post and its intermediate wires bearing against one side of the post and a brace for the post, detachably connected to said upper wire, substantially as described.

700,075. MACHINE FOR DRAWING IN WARP-THREADS. EUGEN FALDER, Grubbi, Germany. Filed Sept. 26, 1902. Serial No. 20,800. (No model.)

Claim.—In a machine for drawing in warp-threads, the combination with a frame, of a rod horizontally arranged therein, the vertically-movable knives arranged one above the other, and means for operating said knives, and the bottom knife having a notch for the reception of the warp-thread, substantially as described.

700,076. LIVE-WOOD WALL FOR LEVERING. JAMES PATTON, New York, N. Y. Filed Mar. 12, 1900. Serial No. 674,265. (No model.)

Claim.—1. A live-wood wall composed of live trees or other long-lived wood plants which were assembled, fastened together and planted substantially as herein described and for the purposes set forth.

2. A live-wood wall composed of trees (or other long-lived wood plants) which were trimmed or flattened where they were joined before they were assembled, fastened together and planted, substantially as herein shown and for the purposes herein set forth.

3. An X-shaped live-wood wall composed of live trees (or other long-lived plants) which were arched, assembled X-shaped in a double row, fastened together and planted, substantially as herein described and for the purposes set forth.

4. A live-wood-wall pipe composed of live trees (or other long-lived wood plants) which were trimmed or flattened beneath the bark on the sides where they join before they were assembled, fastened together and planted substantially as described and for the purposes set forth.

5. A live-wood wall composed of live trees (or other wood plants) assembled, fastened together and planted substantially as described, in combination with sufficient earth deposited between or against the live-wood wall to form a levee or embankment, substantially as described and for the purposes set forth.

6. A system of live-wood walls composed of live trees (or other long-lived wood plants) assembled, fastened together and planted substantially as described so as to form retaining-walls for the dikes and terraces of

levees or embankments, substantially as described and for the purposes set forth.

700,077. FEATHER-POKE. FRANK A. FERRIS, Seattle, Wash. Filed Dec. 20, 1901. Serial No. 57,777. (No model.)

Claim.—1. A metallic post which is imperforate, a resistance-plate having a concave face with a shoulder at its lower pointed end, the lower end of said post adapted to rest on the shoulder of said resistance-plate, a threaded bolt with hooked end passing through said plate and holding the latter to the post and a resistance-plate fastened to the opposite edge of the post and above the plate fastened to the bottom of the post, as set forth.

2. A metallic post, a resistance-plate having a shoulder near its tapered end, a threaded bolt with hooked end passing through an aperture in said plate and designed to hold the plate to the post, said plate being concave on one face and notched to receive the edge of the post, a resistance-plate having its opposite sides concave, oppositely-disposed notches or grooves on one side thereof, a threaded bolt adapted to engage over the edge of the post and designed to hold the plate with concave face on the opposite edge of the post from that engaged by the plate at the lower end of the post, as set forth.

700,078. FEATHER-CLEANING MACHINE. HARRY W. FERRY, FARMER, Allegheny, Pa. Filed Jan. 2, 1902. Serial No. 55,301. (No model.)

Claim.—1. A feather-cleaning apparatus consisting of an outer surrounding case provided with an suction-pipe, an inner revolving perforated drum, a series of revolving beater-arms in the interior of the drum, means for rotating the drum and beater-arms in opposite directions, and a blower in communication with the interior of the case, and provided with an adjustable speed adapted to be connected with the drum to withdraw the feathers therefrom.

2. A feather-cleaning apparatus consisting of an outer surrounding case provided with an suction-pipe, an inner revolving perforated drum, a series of revolving beater-arms in the interior of the drum, means for rotating the drum and beater-arms in opposite directions, and a blower provided with an inlet-duct leading to the interior of the case, a

discharge-duct adapted to communicate with the interior of the drum, a valve, and a discharge-pipe.

3. A feather-cleaning apparatus consisting of an outer surrounding case provided with an suction-pipe, an inner revolving perforated drum, a series of revolving beater-arms in the interior of the drum, means for rotating the drum and beater-arms in opposite directions, an air-inlet-duct leading to the interior of the case, a suction-duct adapted to communicate with the interior of the drum, a discharge-pipe and means for supplying a current of air to the case and for establishing a suction-current through the suction-duct and the discharge-pipe.

4. A feather-cleaning apparatus consisting of an outer surrounding case provided with an suction-pipe, a central shaft provided with laterally-arranged beater-arms, a surrounding drum within the case journaled around said shaft and provided with curved-sections, means for rotating the drum and beater-arms in opposite directions, and a blower provided with a discharge-pipe leading to the interior of the case and a suction-pipe adapted to communicate with the interior of the drum, with a valve-controlled discharge-pipe.

5. In a feather-cleaning machine provided with a revolving drum having a series of curved-sections, a slide-covered opening in one of said sections, and a suction-pipe adapted to communicate therewith to establish communication with a discharge-pipe, with means for establishing a suction-current therethrough.

6. In a feather-cleaning machine, the combination of an outer surrounding case provided with an suction-pipe, an inner revolving drum provided with a series of removable perforated sections, a central shaft provided with a series of radial beater-arms, means for rotating the drum and central shaft in opposite directions and at different speeds, a blower device communicating with the interior of the case adapted to discharge a current of air against the sections, an opening in one of the sections, and a suction-pipe adapted to communicate therewith with the interior and adapted to act as an outlet-duct for the sections of the drum.

700,079. POTENTIAL-REGULATOR. ROBERT A. PHILLIP, Seattle, Wash. Filed Nov. 6, 1901. Serial No. 51,120. (No model.)

Claim.—1. A system of the kind described, comprising main, pilot-wire and potential-transformers, said potential-transformers having primary circuits arranged in multiple and connected with said main, and having secondary circuits arranged in series and connected with said pilot-wire.

2. A system of the kind described, comprising main, pilot-wire and potential-transformers, said potential-transformers being arranged in multiple and connected with said main, and having secondary circuits arranged in series and connected with said pilot-wire, the primary and secondary coils of one transformer having a ratio of potential differing from those of another transformer for the purpose of modifying the main potential of both of said transformers.

3. A system of the kind described, comprising main, pilot-wire, potential-transformers and shunt-wire, said potential-transformers having primary circuits connected with said main, secondary circuits connected with said pilot-wire, and said shunt-wire directly connecting said main

and said pilot-wires, the potential of said steam-circuit thus formed being a component of the potential reported by said pilot-wires.

4. A system of the kind described, comprising pilot-wires, potential-transformers, and primary and secondary mains, some of said transformers having their secondary circuits arranged in series and connected with said pilot-wires, their primary circuits being arranged in multiple and connected to said primary mains and also to the said secondary mains, said secondary mains being in turn connected to the secondary coil of another of said transformers, the primary coil of which is connected to said primary mains.

5. A system of the kind described, comprising main, pilot-wires, transformers provided with primary and secondary coils, said primary coils being connected in parallel with said mains for the purpose of averaging the potential thereof, said pilot-wires being connected with said secondary coils for reporting a potential proportionate to the average voltage of said primary coils.

6. A system of the kind described, comprising pilot-wires, transformers provided with primary and secondary coils, said primary coils being connected in parallel with said mains, and means connected with said secondary coils for indicating various degrees of potentials proportionate to the average potentials of said primary coils.

700,080. STEAM HEATING APPARATUS. GEORGE S. PHILLIPS, Albany, N. Y. Filed Aug. 14, 1898. Serial No. 690,265. (No model.)

Claim.—1. In a drying apparatus, an inclosure having a series of inlet-openings and discharge-passage, a series of vertical radiator-coils arranged within the inclosure, and a series of fans arranged to receive cold air from without, whereby it is independent currents spirally between the coils and discharge it while hot but before the temperature rises too high to effect condensation, and thereby insuring a partial vacuum on the exhaust side of the engine, as set forth.

2. In a drying apparatus a series of vertical radiator-coils, an inclosure therefor having a series of inlet-openings and discharge-passage, a series of fans arranged to receive cold air from without, whereby it is independent currents spirally between the coils and discharge it while hot but before the temperature rises too high to effect condensation, whereby a partial vacuum on the exhaust side of the engine is insured, obliquely-disposed partitions in said inclosure, and tracks upon opposite sides of the fan and coils, substantially as shown and described.

700,081. IMPACT-TOOL. THOMAS H. PHILLIPS, St. Louis, Mo. Filed Feb. 12, 1898. Serial No. 69,391. (No model.)

Claim.—1. The combination, in an impact-tool, of the cylinder, the piston having a steam-supplying groove, the valve-chest, the valve having heads of different area, a steam-inlet uncontrolled by the piston for admitting steam to the forward end of the cylinder through the medium of the valve, and a steam-inlet controlled by the piston for admitting steam to the rear end of the cylinder, substantially as specified.

2. The combination, in an impact-tool, of the cylinder, the piston having a steam-supplying groove, the valve-chest, the valve having heads of different area, a steam-inlet uncontrolled by the piston for admitting steam to the forward end of the cylinder through the medium of the valve, and a steam-inlet controlled by the piston for admitting steam to the rear end of the cylinder through the medium of the valve, substantially as specified.

3. The combination, in an impact-tool, of the cylinder, the piston having a steam-supplying groove, the valve-chest, the valve having heads of different area, a steam-inlet uncontrolled by the piston for admitting steam to the forward end of the cylinder through the medium of the valve, a steam-inlet controlled by the piston for admitting steam to the rear end of the cylinder through the medium of the valve, and a steam-inlet controlled by the piston for admitting steam to the rear end of the cylinder through the medium of the valve, substantially as specified.

by the piston for admitting steam to the rear end of the cylinder through the medium of the valve, substantially as specified.

4. The combination in an impact-tool, of the cylinder, the piston having a steam-supplying groove, the valve-chest, the valve having heads of different area, and parts and passages whereby the rearward movement of the valve is effected by full-pressure steam acting upon its larger forward head against full-pressure steam acting upon the smaller rear head, and forward movement of the valve is effected by full-pressure steam acting upon said smaller rear head against expanded steam acting upon the larger forward head, substantially as specified.

5. The combination in an impact-tool, of the cylinder, the piston having a steam-supplying groove, the valve-chest, the valve having heads of different area, parts and passages whereby said valve controls admission of steam to the front end of the cylinder and exhaust of steam from both ends of the cylinder, and other parts and passages whereby the rearward movement of the valve is effected by full-pressure steam acting upon its larger forward head against full-pressure steam acting upon the smaller rear head, and forward movement of the valve is effected by full-pressure steam acting upon said smaller rear head against expanded steam acting upon the larger forward head, substantially as specified.

6. The combination in an impact-tool, of the cylinder, the piston having a steam-supplying groove, the valve-chest, the valve having heads of different area, parts and passages whereby said valve controls admission of steam to and exhaust of steam from each end of the cylinder, and other parts and passages whereby the rearward movement of the valve is effected by full-pressure steam acting upon its larger forward head against full-pressure steam acting upon the smaller rear head, and forward movement of the valve is effected by full-pressure steam acting upon said smaller rear head against expanded steam acting upon the larger forward head, substantially as specified.

7. The combination in an impact-tool, of the cylinder, the piston having a steam-supplying groove, the valve-chest, the valve having central piston and forward and rear heads, said rear head being of less diameter than the central piston and forward head, and parts and passages whereby rearward movement of the valve is effected by live-steam pressure acting upon the forward head in opposition to live-steam pressure acting upon the rear head, and forward movement of the valve is effected by live-steam pressure acting upon the rear head assisted by expanded pressure in the chamber between the central piston and rear head, and opposed by expanded pressure acting upon the forward head, substantially as specified.

8. The combination in an impact-tool, of the cylinder, the piston having a steam-supplying groove, the valve-chest, the valve having central piston and forward and rear heads, said rear head being of less diameter

than the central piston and forward head, parts and passages whereby said valve controls admission of steam to the forward end of the cylinder, and exhaust of steam from both ends of the cylinder, and other parts and passages whereby rearward movement of the valve is effected by live-steam pressure acting upon the forward head in opposition to live-steam pressure acting upon the rear head, and forward movement of the valve is effected by live-steam pressure acting upon the rear head assisted by expanded pressure in the chamber between the central piston and rear head, and opposed by expanded pressure acting upon the forward head, substantially as specified.

9. The combination in an impact-tool, of the cylinder, the piston having a steam-supplying groove, the valve-chest, the valve having central piston and forward and rear heads, said rear head being of less diameter than the central piston and forward head, parts and passages whereby said valve controls admission of steam to and exhaust of steam from each end of the cylinder, and other parts and passages whereby rearward movement of the valve is effected by live-steam pressure acting upon the forward head in opposition to live-steam pressure acting upon the rear head, and forward movement of the valve is effected by live-steam pressure acting upon the rear head assisted by expanded pressure in the chamber between the central piston and rear head, and opposed by expanded pressure acting upon the forward head, substantially as specified.

10. The combination in an impact-tool, of the cylinder, the piston having a steam-supplying groove, the valve-chest, the valve having a forward head of greater area than the rear head, parts and passages whereby said valve controls admission of steam to and exhaust of steam from both ends of the cylinder, a steam-inlet to the rear end of the cylinder controlled by the piston independently of the valve, and parts and passages whereby on the rearward movement of the piston steam under full pressure is conveyed to the forward end of the valve-chest from the cylinder, before the uncovering of said direct steam-passage, and on the forward movement of the piston, steam under full pressure is maintained in the rear end of the valve-chest, after the cutting off of the inlet of steam to the rear end of the cylinder, substantially as specified.

11. The combination of the cylinder and piston of an impact-tool, with a packing-ring fitting snugly upon said piston but free to move laterally with the same in the cylinder, said ring having a flange bearing against a corresponding flange in the cylinder, substantially as specified.

12. The combination of the cylinder and piston of an impact-tool, with a packing-ring fitting snugly upon said piston but free to move laterally with the same in the cylinder, said ring having a flange bearing against a corresponding flange in the cylinder and having its opposite flange beveled, substantially as specified.

13. The combination in an impact-tool, of the cylinder having an enlarged rear bore, a bushing fitted in said enlarged bore, a piston working within said bushing and having fitted to it a packing-ring which is free to play laterally to a limited extent within the cylinder and occupies a chamber between a shoulder in the cylinder and the bushing, substantially as specified.

14. The combination in an impact-tool, of the cylinder having an enlarged rear bore, a bushing fitted in said enlarged bore and having a central forward end, a piston working within said bushing, and a packing-ring fitted to said piston and having a slight lateral play in the central bore of the bushing, substantially as specified.

15. The combination in an impact-tool, of the cylinder, the piston having a rear head and a groove in advance of the same, a packing-ring fitting upon said rear head of the piston and free to move laterally with the same in the cylinder, but confined longitudinally between shoulders in said cylinder, and ribs on the grooved portion of the piston for supporting said ring when the piston-head leaves the same, substantially as specified.

700,082. ARMOR. JOHN J. PHILIP, Chicago, Ill. Filed Aug. 1, 1891. Serial No. 79,000. (No model.)

Claim.—1. Armor comprising plates each having yieldable arms which have bearing against a suitable backing and against adjacent armor-plates, as and for the purposes set forth.

2. An armor, comprising armor-plates, and spring-arms thereon, projecting laterally to rest on the side of the vessel and thereby yieldingly support an armor-plate and form an abutment for the same, each spring-arm also forming a support for an adjacent armor-plate, as set forth.

3. An armor, comprising armor-plates having their ends provided with integral spring-arms extending laterally, and chains on which the spring-arms are slidably held, as set forth.

4. An armor, comprising armor-plates having their ends provided

with integral spring-arms extending laterally, and chains on which said spring-arms are slidably held, said arms having extensions for supporting the next adjacent armor-plate a distance from the end thereof, as set forth.

5. An armor, comprising armor-plates each having laterally-projecting spring-arms at each end, each spring-arm being formed with a flange and an extension having a head, chain and boys for receiving and holding the flange of the spring-arm, and boys and guides on the armor-plates for receiving the grooved heads of the spring-arms of an adjacent plate, as set forth.

6. Armor comprising plates each having yieldable arms disposed in crossing relation, means for movably confining said arms against a suitable backing, and means whereby the arms of one plate are movably connected with an adjacent plate or plates.

7. Armor comprising plates each having a series of yieldable arms which are fashioned to produce thereon two points of bearing, one of which points of each arm engages with a suitable backing and the other point of bearing engaging with an adjacent armor-plate.

8. Armor comprising plates each having yieldable arms disposed in crossing relation to arms on adjacent plates, a suitable foundation or backing, means for slidably holding said arms on the foundation, and other means for heavily confining the free ends of said arms on the rear sides of the armor-plates.

700,083. PHOTOGRAPHIC-SHUTTER-CONTROLLING DEVICE. JAMES F. PHILLIPS, Charleston, S. C. Original application filed July 14, 1898, Serial No. 24,978. Divided and this application filed Feb. 27, 1899. Serial No. 69,180. (No model.)

Claim.—1. The combination with a photographic shutter adapted to be opened in open position, and mechanism for actuating said shutter; of an electric circuit, device therein electrically actuated, a photo-electric cell, means for rendering the cell conductive in decreasing intensity during the time of exposure, thereby moving said device to cause the shutter-actuating mechanism to close the shutter, substantially as and for the purposes set forth.

2. The combination with a photographic shutter and its actuating mechanism, of an electric circuit, device therein electrically actuated, a photo-electric cell in said circuit and means for rendering said cell conductive in decreasing intensity, thereby moving said device to cause the operation of said shutter-actuating mechanism, substantially as set forth.

3. The combination with a photographic shutter, of electrically-controlled detent mechanism holding said shutter open, an electric circuit containing a photo-electric cell organized to close circuit to operate device to release the detent mechanism, thereby closing the shutter, substantially as set forth.

4. The combination with a photographic shutter, of circuit-closing device, a photo-electric cell electrically connected therewith, an auxiliary circuit, electrically-controlled shutter-detent mechanism therein, said circuit-closing device arranged to send current to actuate the shutter-detent mechanism, substantially as set forth.

5. The combination with a photographic shutter and its actuating mechanism, of a circuit and means for electrically releasing the shutter-actuating mechanism, a parallel circuit, a photo-electric resistance and circuit-closing device therein, and means for admitting light to said cell, thereby actuating the circuit-closing device to send current to release the shutter-actuating mechanism, substantially as set forth.

6. In combination with a source of electricity, a circuit, a solenoid and a circuit cell in series in said circuit, a second circuit, a circuit-closing switch and electrically-operated means to cause the actuation of a photographic shutter in said second circuit, substantially as set forth.

7. In combination, a photographic shutter, a source of electricity, a circuit containing a switch and electrically-operated means to cause the actuation of the photographic shutter, a second circuit divided into two branches, each branch containing a solenoid and a photo-electric resistance, said solenoid arranged to operate said switch, substantially as and for the purposes set forth.

8. In combination, a photographic shutter, a source of electricity, a circuit, a switch and electrically-operated means to cause the actuation of the photographic shutter, a second circuit divided into two branches, a solenoid coil, and a solenoid in series in each branch, means for temporarily causing one coil to be of a different resistance from

the other, a core common to both solenoids and arranged to operate said solenoid, substantially as set forth.

9. In combination, a photographic shutter, a source of electricity, a circuit, a switch and electrically-operated means in the circuit to cause the extension of said shutter, a second circuit divided into two branches, each containing a solenoid coil and a solenoid, movable core common to said solenoids, the latter arranged for differential action, said core arranged to operate the switch and means to cause a difference of resistance in said coils, substantially as set forth.

10. The combination with a pneumatic photographic shutter, of a source of electricity, a circuit, a switch and shutter-detent mechanism therein, a second circuit divided into two branch circuits, each containing a solenoid coil and a solenoid, means for causing a differential action of said solenoid by varying the conductivity of one of the coils relatively to the other and core for said solenoid arranged to close the first-mentioned circuit, substantially as set forth.

11. The combination with a photographic shutter, of a source of electricity, a circuit, electrically-operated shutter-releasing mechanism therein, a second circuit, a photo-electric resistance and a circuit-closer therein, and device for intermittently admitting light to said coil, thereby actuating the circuit-closer to release the shutter, substantially as set forth.

12. The combination with a photographic shutter, of a source of electricity, a circuit, electrically-operated shutter-detent mechanism therein, a second circuit, a photo-electric coil and circuit-closer therein, means for intermittently admitting light to said coil and auxiliary means for decreasing the intensity of said light, thereby actuating the circuit-closer to send current through the first-mentioned circuit and release the shutter, substantially as set forth.

13. The combination with a photographic shutter, of a source of electricity, a circuit containing electrically-operated shutter-detent mechanism, two branch circuits each containing a solenoid coil and both of said circuits arranged to differentially operate a circuit-closer, mechanism for intermittently admitting light to each of said coils and a device for gradually decreasing the action of light on one of said coils, thereby actuating the circuit-closer to send current through the first-mentioned circuit to release the shutter, substantially as set forth.

14. The combination with a photographic shutter, of a source of electricity, a circuit containing electrically-operated shutter-detent mechanism, two circuits in parallel with the first circuit, each containing a solenoid coil, a differentially-operated circuit-closer in said parallel circuit, a perforated diaphragm moved past said coils, means for admitting light of decreasing intensity to one end of constant intensity to the other of said coils and through the opening in said diaphragm, substantially as set forth.

15. The combination with a photographic shutter, of a source of electricity, a circuit, electrically-operated detent mechanism and a pair of contacts therein, two circuits in parallel with the first circuit, a solenoid coil and a solenoid in each of the two parallel circuits, said contacts arranged to be closed by said solenoid, a rotating perforated diaphragm moved past said coils, means for admitting light of decreasing intensity to one end of constant intensity to the other of said coils through the opening in the diaphragm, substantially as set forth.

16. The combination with a photographic shutter, of an electric circuit, electrically-operated shutter-detent mechanism and a pair of contacts therein, a second circuit, a photo-electric resistance and a solenoid arranged to operate the mechanism to close said circuit, a perforated diaphragm moved past said coils, means for reflecting light from an actinic medium through the perforation to said coil, substantially as set forth.

17. The combination with a photographic shutter, of an electric circuit, electrically-operated shutter-detent mechanism and a solenoid in the latter circuit arranged to open and close said circuit, a perforated diaphragm mechanically revolved past and whose perforations register with said coil, means for reflecting light to an actinic body and from the latter through the perforations to said coil, substantially as set forth.

18. The combination with a photographic shutter, of an electric circuit, electrically-operated shutter-detent mechanism and a pair of contacts therein, means for opening said contacts to vary the time of exposure, two branch circuits in parallel, a solenoid and photo-electric coil in each of the branch circuits, a perforated rotating disk, the perforations therein rotatable past said coil, a clockwork for moving said disk and means for reflecting light from an invariable reflector near each coil to an actinic reflector at one end and a reflector of constant color at the other end from said last reflector through the rotating diaphragm in the respective coils, substantially as set forth.

19. The combination with a photographic shutter, of an electric circuit, a solenoid coil acting as electric conductor when subjected to light and as resistance when withdrawn from light, a sensitive body darkening by the action of light and placed between the solenoid coil and the light,

an electrically-operated shutter-detent mechanism in such connection with the solenoid coil that on the change of the electric circuit the detent is released and the shutter closed.

20. The combination with a photographic shutter and its actuating mechanism, of electrically-operated means for controlling the operation of the shutter and a photo-electric resistance operatively combined with said means, whereby exposure is made in accordance with the intensity of the light, substantially as set forth.

21. The combination with a photographic shutter and its actuating mechanism, of electrically-operated means for controlling the operation of said shutter and a pair of photo-electric resistances, the combined action of which is differential, operatively combined with said means, whereby exposure may be regulated in accordance with the intensity of light, substantially as set forth.

700,084. TRACK. JOHN R. GUNN, Chicago, Ill. Filed July 18, 1891. Serial No. 67,718. (No model.)

Claim.—1. In a track system, the combination with two parallel rails forming a portion of a single track, of three parallel rails a short distance therefrom, the middle rail of which is adapted for use with either of the outer rails, and connecting-rails between both rails of the single track and the middle rail being provided with means whereby they may be brought alternately into use to connect the single track with either side of the three-rail track, substantially as described.

2. In a track system, the combination with two parallel rails separated to the extent of the track-gage and having diverging extensions, separating to substantially twice said gage and thereafter extending in parallel direction, of a third rail between the latter parallel portions and equidistant therefrom, and movable connection between said middle rail and each of the former parallel portions of the two rails, said movable portions being capable of alternate movement toward their respective side rails to connect the latter with the middle rail; substantially as described.

3. The combination with a two-rail track, of a double three-rail track formed by a continuation of the rails of the two-rail track, diverging to twice the distance and a third rail intermediate and equidistant therefrom, a pair of split-joint switch-rails, moving alternately into engagement with the rails of the two-rail track and leading therefrom toward the middle rail and a bent reversible connecting portion adapted, when placed in the proper position, to connect either of the switch-rails with the middle rail; substantially as described.

700,085. MICROSCOPE-CALIPERS. GEORGE H. HADENLIFE, Derby, Conn. Filed Jan. 21, 1902. Serial No. 80,000. (No model.)

Claim.—A measuring instrument comprising two members and means whereby one may be adjusted toward and from the other, one of

said members having a depression in its side said depression being adapted to receive one point of compass or divider and to retain that point against lateral displacement, and the other member having a groove to receive the other point of the compass or divider.

700,086. DUMPING-WAGON. PHILIP KEMM, Hops, Ohio. Filed Oct. 13, 1891. Serial No. 73,302. (No model.)

Claim.—1. In a dumping-wagon, the combination with the frame provided with longitudinal slots in its side bars, and the wagon-body; of parallel shafts mounted below the wagon-body and having their ends projecting through said slots, and having enlarged central portions, a pair of toggle-arms at each side of the wagon connecting said shafts and pivoted to the sides of the wagon-body, a screw extending through the enlarged portions of said parallel shafts, and means for revolving said screw.

2. In a dumping-wagon, the combination with the frame provided with longitudinal slots in its side bars, and the wagon-body; of parallel shafts mounted below the wagon-body and having their ends projecting through the said slots, a pair of toggle-arms at each side of the wagon connecting said shafts and pivoted to the sides of the wagon-body, a block having an unthreaded opening arranged centrally on one of said shafts, a block having a threaded opening arranged centrally on the other shaft, and a screw through the said blocks whereby the wagon-body will be raised and then moved rearward.

3. In a dumping-wagon, the combination with a supporting frame having rollers mounted at its rear end and having side bars formed with longitudinal slots; of two parallel shafts, the ends of which project through said slots, a pair of toggle-arms at each side of the wagon-body connected to the ends of said shafts and pivoted to the sides of the wagon-body, a block formed with an unthreaded opening centered on one shaft, a nut centered on the other shaft, a screw extending through said nut, and means for operating said screw.

700,087. PIPE-WRENCH. HENRY F. SUMNER, Erie, Pa., assignor to Hollands Manufacturing Company, Erie, Pa., a Corporation. Filed Dec. 20, 1891. Serial No. 67,890. (No model.)

Claim.—1. The combination in a pipe-wrench, of a handle, a fixed jaw on the end thereof, a sliding jaw resting against the handle so that it will rest slightly thereon, an internally-threaded shank extending the sliding jaw and the handle immediately behind the fixed jaw thereon so as

to hold the two jaws in place, and a thread on the back of the sliding jaw engaging the thread in said shank, substantially as set forth for the purpose set forth.

2. The combination in a pipe-wrench, of a fixed jaw, a handle thereon having a room in its outer face back of the jaw thereon, a curved surface on the handle, a sliding jaw contacting with said curved surface, a thread on the outer face of the sliding jaw, and an internally-curved threaded shank extending the handle at the room therein and also the sliding jaw, and engaging the thread thereon, substantially as set forth for the purpose set forth.

700,088. WATER-PIPE. WILLIAM KEMMER, Gerdau, Germany, assignor to August Volpert, Gerdau, near Elm, Germany. Filed Aug. 20, 1891. Serial No. 73,303. (No model.)

Claim.—1. In a device of the class described, the combination with a pipe-bowl, of a water-reservoir, and means for directing the passage of the smoke from the bowl through the water in the reservoir, and for subjecting the same to the drying action of the tobacco burning in the bowl after its passage through the water in the reservoir, substantially as shown and described.

2. In a device of the class described, the combination with a pipe-bowl, of a water-bottle, a smoke-conduit in communication at one end with the pipe-bowl and at the other with the water-bottle below the level of the water therein, and a smoke-conduit in communication at its inlet end with the water-bottle above the water-level thereof, a portion of which conduit is in such proximity to the pipe-bowl as to be heated by the combustion of the tobacco therein, whereby the smoke is heated and dried after its passage through the water, substantially as shown and described.

3. In a device of the class described, the combination with a pipe-bowl, of a water-reservoir, a smoke-conduit leading from the bowl to the reservoir and in communication therewith below the water-level thereof by way of a plurality of orifices, substantially as shown and described.

4. In a device of the class described, the combination with a pipe-bowl, of a water-reservoir, a smoke-conduit leading from the bowl to the reservoir and in communication therewith below the water-level thereof, and means located at the outlet end of the conduit for breaking up the smoke into a plurality of small streams as it passes from the conduit, substantially as shown and described.

5. In a device of the class described, the combination with a pipe-bowl, of a water-reservoir, a smoke-conduit leading from the bowl to the reservoir and in communication therewith below the water-level thereof, and an enlarged portion or stiller-plate open at the bottom and provided with a perforate wall forming the end of the smoke-conduit within the water-reservoir, substantially as shown and described.

6. In a device of the class described, the combination with a pipe-bowl, of a water-reservoir, means for directing the passage of the smoke from the pipe-bowl through the water in the reservoir, means for subjecting the smoke to the heating action of the tobacco burning in the bowl after its passage through the water, a condenser located in the reservoir below the water-line thereof, and means for passing the smoke through the condenser after it has been subjected to the heating action of the pipe-bowl, substantially as shown and described.

7. In a device of the class described, the combination with a pipe-bowl, of a water-reservoir, means for directing the passage of the smoke from the pipe-bowl through the water in the reservoir, means for subjecting the smoke to the heating action of the tobacco burning in the bowl after its passage through the water, a condenser located in the reservoir below the water-line thereof, a stop-cock for the condenser, and means for passing the smoke through the condenser after it has been subjected to the heating action of the pipe-bowl, substantially as shown and described.

8. A water-pipe composed of the water-reservoir A, the pipe-bowl B, the perforated stiller F in communication with the bowl by a tube E, a tube G by which the heated smoke is circulated around the bowl

B and again through the water into the condenser H, and pipe-stem D forming a communication between the condenser and the manhole C, substantially as shown and described.

700,089. VEHICLE-BRAKE. JOHN D. EDWARDS, Wheeling, Ind., assignor of one-half to Edward G. Edwards and Elmer Baker, Wheeling, Ind. Filed Dec. 2, 1901. Serial No. 94,394. (No model.)

Claim.—In a vehicle-brake the combination with the brake-shoe of brake-rods connected thereto, loops in said brake-rods, springs secured thereto, the whole arranged whereby, the loops engage the shafts and prevent the brake-rods from turning when the vehicle is moving forward, and which form cranks to draw the said brake-rods into their normal position after the brake-shoes are raised by the backing of the vehicle substantially as described.

700,090. PROCESS OF COLORING MARBLE STONE, OR THE LIKE. WILLIAM S. BROWN and ALBERT C. BROWN, Cincinnati, Ohio, assignors of three-fifths to Henry C. Yelver and Otto H. L. Wernicke, Cincinnati, Ohio. Filed Feb. 17, 1902. Serial No. 94,502. (No specific claim.)

Claim.—1. The process of coloring marble stone and the like, which consists in first heating the stone to a temperature of about 215° Fahrenheit, and then applying the dye dissolved in oil to permeate the pores of the material, substantially as described.

2. The process of coloring marble stone and the like, which consists in first heating the stone to a temperature of about 215° Fahrenheit, and then applying the dye dissolved in oil to permeate the pores of the material, then coating the surface with paraffin to fix the color, substantially as described.

700,091. WATER-TUBE BOILER. ROBERT C. YOUNG, Pueblo, Colo. Filed Nov. 1, 1901. Serial No. 91,499. (No model.)

Claim.—1. In a water-tube boiler, the combination of a furnace, upper and lower drums, a number of series of straight tubes connecting said drums, the latter being constructed with a series of pressed-out plane surfaces tangent to their curved surface, the same being constructed to permit the entrance in the same plane of all the tubes in each series perpendicular to both the interior and exterior surface of said pressed-out portions without bending, a stack, means for causing the products of combustion to circulate around the tubes and drums as they pass from the furnace to said stack, substantially as described.

2. As a new article of manufacture, a tube-sheet for a water-tube boiler, the same having portions of its surface pressed out to form a series of plane surfaces, each one of said surfaces being tangent to the curve of

the tube-sheet and having an unflared curved portion of said tube-sheet between it and the pressed-out surface next adjacent, substantially as described.

3. In a water-tube boiler, the combination of a furnace, upper and lower drums each having its curved surface pressed out so as to form a number of successive plane surfaces all in the same plane and separated from the plane surface on each side of it by an unflared curved section of the drum-surface, series of tubes extending between the drums, all the tubes of each series entering a single one of said plane surfaces, a stack and means for causing the products of combustion to circulate around said tubes during their passage from the furnace to the stack, substantially as described.

4. The combination in a water-tube boiler, of a casing, a series of lower drums, a series of upper drums, straight tubes connecting each of the upper drums with one of the lower drums, the vertical boiler-tubes between the sets of tubes arranged across the combustion-chamber of the structure, having means whereby they are supported independently of said tubes and drums, a furnace-section connected with one end of the combustion-chamber and a stack connected to the other end of the same, substantially as described.

5. As a new article of manufacture, a tube-sheet for a water-tube boiler, the same having portions of its surface pressed out to form a series of plane surfaces, each one of said surfaces having an unflared curved portion of said tube-sheet between it and the pressed-out surface next adjacent, substantially as described.

700,092. APPLIANCE FOR TAKING UP OR NEUTRALIZING SHOCKS. FRIEDRICH H. SCHMIDT, Hamburg, Germany. Filed Jan. 2, 1904. Serial No. 94,514. (No model.)

Claim.—1. The combination with a body to be reciprocated and an element, as a crank-driven connecting-rod, for reciprocating said body; of

means for neutralizing shocks, comprising a carrier journaled to said body and mounted loosely on the connecting-rod, and provided with cross-head guides, a cross-head guided thereby and secured to the rod, and yielding resistance acting at different points on said cross-head to antagonize its movements with the connecting-rod, the degree of resistance varying substantially in accordance with the moment on the cross-head at said different points, for the purpose set forth.

2. The combination with a body to be reciprocated and an element, as a crank-driven connecting-rod, for reciprocating the same; of means for neutralizing shocks, comprising a carrier in the form of a frame journaled to the abovementioned body at points intermediate of its longitudinal center and that end furthest from the driven end of the rod, said carrier having cross-head guides, a cross-head secured to the connecting-rod and guided by said guides, and yielding resistance acting on opposite faces of the cross-head at different points to antagonize its to-and-fro movements with the connecting-rod, the power exerted by said resistance varying substantially in accordance with the moment on said cross-head at said different points, for the purpose set forth.

3. The combination with a body to be reciprocated and an element, as a crank-driven connecting-rod, for reciprocating the same; of means for neutralizing shocks comprising a carrier loosely mounted on the rod and journaled to the abovementioned body at points intermediate of its longitudinal center and that end furthest from the driven end of the rod, said carrier having cross-head guides, a cross-head secured to the connecting-rod and guided by said guides, and yielding resistance acting on opposite faces of the cross-head at different points to antagonize its to-and-fro movements with the connecting-rod, the power exerted by said resistance varying substantially in accordance with the moment on said cross-head at the abovementioned different points, for the purpose set forth.

4. The combination with a body to be reciprocated and an element, as a connecting-rod, for reciprocating the same; of a carrier in the form of a frame, loosely mounted on the rod and journaled to the abovementioned body at points intermediate of its longitudinal center and that end furthest from the driven end of the rod, guide-rods secured to said frame, a cross-head secured to the connecting-rod and having free motion on the guide-rods, and yielding resistance on said rods antagonizing the movements of the cross-head with the connecting-rod, the power exerted by said resistance varying substantially in accordance with the moment on the cross-head at the various points acted on by the resistance, for the purpose set forth.

5. The combination with a separator and a to-and-fro movable connecting-rod; of the frame F loosely mounted on said rod and having journal F' journaled in bearings on and about midway of the length of the separator-support, guide-rods G, secured to the ends of said frame, the cross-head H secured to the connecting-rod and guided on rods I, springs U, V, W, secured on opposite sides of the cross-head, and the buffer B and B' interposed between the cross-head and the springs U, V, W, respectively, substantially as and for the purpose set forth.

6. The combination with a body to be reciprocated and an element, as a crank-driven connecting-rod, for reciprocating the same; of means for neutralizing shocks comprising a carrier loosely mounted on the rod and journaled to the abovementioned body at points intermediate of its longitudinal center and that end furthest from the driven end of the rod, said carrier having cross-head guides, a cross-head secured to the connecting-rod and guided by said guides, and yielding resistance acting on opposite faces of the cross-head at different points to antagonize its to-and-fro movements with the connecting-rod, substantially as and for the purpose set forth.

700,093. FISHING DEVICE. JAMES SMITH, South Norwalk, Conn. Filed Sept. 20, 1901. Serial No. 77,894. (No model.)

Claim.—1. The combination of a body, means for attaching a line thereto, said means comprising a pointed spur with an eye therein, and hooks attached to the body and projecting outward therefrom with their points in direction of the line.

2. A fishing appliance, comprising a body, a shaft fastened to the top of the body in the vertical center thereof, the shaft curving to carry the fishing-line, hooks rigidly attached to the body and projecting outward radially therefrom, the hooks having their points extending in direction of the line, and a bait-spur attached to the body and projecting upward therefrom alongside of the shaft.

700,094. HARVESTER-KNIFE. BEN AME GULPE, Winchester, Ohio. Filed Oct. 7, 1901. Serial No. 77,907. (No model.)

Claim.—1. In a harvester, the combination with a collapsible reel, means for expanding the same, and a slideable rack, of a frame mounted on the reel-shaft, and having the rack fitted therein, a pinion in mesh with the rack, and an adjusting-rod fitted in the frame and clatched to the pinion, as set forth.

2. In a harvester, the combination with a reel-shaft, a spring-coiled reel, and a rack for expanding the reel, of a slideable and revolvable adjusting-rod, a pinion in mesh with said rack and clatched to said adjusting-rod, and means for holding said rod and the pinion in operative relation to each other and to the rack.

3. In a harvester, the combination with a reel-shaft, a spring-coiled reel, and a rack for expanding the reel, of a pivoted hanger in which the reel-shaft is journaled, a lever having a pivoted yoke, an adjusting-rod slideably fitted in said yoke and a pinion clatched to the adjusting-rod and meshing with the reel-expanding rack.

4. In a harvester, the combination with a reel-shaft, a spring-coiled reel, and a rack for expanding the reel, of a frame on the reel-shaft, an adjusting-rod revolvably fitted in said frame, a spring acting against said rod to hold it in one position, and a pinion clatched to the rod and meshing with said rack, whereby the reel may be drawn against the energy of the spring and released from engagement with the pinion.

5. In a harvester, the combination of a pivoted hanger, a collapsible reel having its shaft mounted therein, an expanding rack in operative relation to the reel, a revolved yoke, an adjusting-rod having a polygonal portion fitted slideably in the yoke, a rubber on said polygonal portion of the rod, a detent engaging said rubber, and a pinion clatched to the adjusting-rod and meshing with the rack.

6. In a harvester, the combination with a reel-shaft, a reel, and a rack, of a frame connected to the reel-shaft, a guide-plate engaging with the rack and fastened adjustably to said frame, an adjusting-rod fitted in the frame, and a pinion clatched to said rod and meshing with the rack.

7. In a harvester, the combination with a reel-shaft, a reel, and a rack, of a frame fitted in the reel-shaft, a slideable and revolvable rod fitted in the frame and having a clutch-pin, a pinion loose on the reel, in engagement with the rack, and having a clutch-finger adapted for engagement with the clutch-pin, and a spring normally impelling the rod to its clutch-pin to make the pinion fast with said rod.

700,095. SAFETY ATTACHMENT FOR POISON BOTTLES. GEORGE J. BERNHARDT, Washington, D. C. Filed Feb. 11, 1902. Serial No. 94,517. (No model.)

Claim.—1. A safety attachment for a poison-containing receptacle having a closing device, consisting of a clip to engage the receptacle and

closing device, and a locking-disk rotatably mounted over the clip and closing device.

2. A safety attachment for poison-containing receptacles and the like having closing devices, consisting of a clip with an upper arcuate portion and depending legs to engage the closing device and rim of the receptacle, and a locking-disk having a slot therethrough with diametrically-opposed extensions.

3. A safety attachment for the purpose set forth comprising a resilient clip having depending legs and a locking-disk with a slot therethrough to engage the said legs.

4. A safety attachment of the class set forth having resilient legs, a poison-indicating insignia movably attached to one of said legs and means for holding the legs in contact with the poison-containing receptacle.

5. A safety attachment of the class set forth comprising a clip having resilient legs with contact ends, and means for contracting the said legs.

700,096. AUTOMATIC SLUICE. WILHELM K. GERTH, Wismar, Germany, and ALFRED F. GERTH, Wismar, Germany. Filed Oct. 7, 1901. Serial No. 77,886. (No model.)

Claim.—1. In an automatic sluice, the combination with a suitable frame, of a transverse shaft therein located nearer the bottom than the top, a straight, normally upright shutter pivotedly mounted on said shaft, the part below the shaft being shorter than the part above, a step to prevent movement of the lower wing of the shutter from the perpendicular in the direction of the flow of the water, a step to prevent movement of the upper wing in the direction opposite to the flow of the water, leaves attached at their upper ends outside of the lower wing, and means whereby said leaves are caused to follow the inward movement of the lower wing and at an acute angle thereto, substantially as described.

2. In an automatic sluice, the combination with a suitable frame, of a transverse shaft therein located nearer the bottom than the top, a straight, normally upright shutter pivotedly mounted on said shaft, the part below the shaft being shorter than the part above, a step to prevent movement of the lower wing of the shutter from the perpendicular in the direction of the flow of the water, a step to prevent movement of the upper wing in the direction opposite to the flow of the water, leaves loosely pivoted at their upper ends outside of the lower wing and normally depending vertically when the wing is vertical, and means for limiting their distance from the lower wing, and from each other, when the wing is moved inward, substantially as described.

3. In an automatic sluice, the combination with a suitable frame, of a transverse shaft therein located nearer the bottom than the top, a straight, normally upright shutter pivotedly mounted on said shaft, the part below the shaft being shorter than the part above, a step to prevent movement of the lower wing of the shutter from the perpendicular in the direction of the flow of the water, a step to prevent movement of the upper wing in the direction opposite to the flow of the water, leaves loosely pivoted at their upper ends outside of the lower wing and normally depending vertically when the wing is vertical, and means for holding the leaves closely against the rear face of the lower wing during any inward movement of said wing, substantially as described.

4. In an automatic sluice, the combination with a suitable frame, of a transverse shaft therein located nearer the bottom than the top, a straight, normally upright shutter pivotedly mounted on said shaft, the part below the shaft being shorter than the part above, a step to prevent movement of the lower wing of the shutter from the perpendicular in the direction of the flow of the water, a step to prevent movement of the upper wing in the direction opposite to the flow of the water, leaves loosely pivoted at their upper ends outside of the lower wing and normally depending vertically when the wing is vertical, a pulley in an opening in the inter-

mediate leaf, a pulley in an opening in the lower wing, a pulley on the inside of the shutter at the height of its shaft, a pulley on the pillar or side wall of the sluice, a chain secured to the inside of the outer leaf and passing about all of said pulleys, and a weight at the end of said chain, substantially as described.

5. In an automatic sluice, the combination with the shutter and the pillars therefor pivoted at their lower ends of a strut longer than the pillars and pivoted at its upper end to the upper ends of the pillars, said strut having its lower end clamped to move freely upon the bottom of the sluiceway, a transverse step on said bottom, a two-armed lever pivotedly attached to the strut near its lower end and the lower arm of said lever being adapted to engage said step when the shutter is raised, a chain attached to the upper arm of said lever, means for pulling said chain, and a screw-spline connected to said chain to securely tighten it, substantially as described.

700,097. GRAIN-LOADER. BENJAMIN F. BLANCH, Pease, N. H. Filed May 24, 1900. Serial No. 17,575. (No model.)

Claim.—1. The combination in a grain-loader, of a portable support, a casing arranged thereon and adapted for tilting adjustment to vary the height of its discharge, said casing being provided with a curved or concave bottom and having discharge-openings at its opposite ends, means for independently closing said openings, the side of the casing being provided with two grain-inlet openings, a pivoted cover for closing either of said openings, and a reversible rotary fan mounted in said casing.

2. The combination in a grain-loader, of a portable support, a shaft mounted in bearings thereon, a casing carried by the shaft and adapted for tilting adjustment, a locking-rod carried by the casing and adapted to slide in the support said casing having discharge-openings at each end, means for independently closing said openings, the side of the casing being provided with two grain-inlet openings, means for closing said openings, and a reversible rotary fan in said casing, substantially as specified.

3. The combination in a grain-loader, of a portable casing provided with a discharge-opening, a fan therein, a bracket hinged to a fixed support, a rod detachably connected to the bracket and adapted to support the casing in position, driving-gearing in part supported by the bracket, a power-transmitting shaft connected by universal couplings to the driving-gearing and to the fan-shaft, the arrangement being such that when the bracket is released the driving mechanism will fall by gravity vertically alongside the fixed support.

700,098. HANDLE-BAR. LAWRENCE K. W. SMITH, New Brighton, N. Y. Filed Mar. 14, 1901. Serial No. 51,157. (No model.)

Claim.—1. In a handle-bar, the combination with a casing, of a worm-gear rotatably mounted within the casing and provided with a concave annular groove having a worm-thread on its surface, of a pair of handle-bar arms pivotedly mounted upon the casing and having inner curved

edges fitting in the annular groove of the stem and provided with worm-teeth that engage the worm-thread of the same.

2. In a handle-bar, the combination with a casing having an open upper end, of a pair of handle-bar arms pivoted upon the casing and having worm-teeth at their inner ends, an operating-stem rotatably mounted in the casing and having a worm-thread that engages the teeth of the arms, retaining means for the stem movably secured to one face of the casing and engaging said stem, and a locking device located upon the other face of the casing and engaging the retaining means to prevent the movement of the stem.

3. In a handle-bar, the combination with a casing having an open upper end, said casing being provided with worm-teeth on its inner and outer faces, of a pair of handle-bar arms pivoted upon the casing and having worm-threads at their inner ends, an operating-stem rotatably mounted in the casing and having a worm-thread that engages the teeth of the arms, a retaining-ring for the stem threaded upon the inner face of the casing and engaging said stem, and a locking-ring threaded upon the outer face of the casing and engaging the retaining-ring to prevent the movement of the stem.

4. In a handle-bar, the combination with a casing having an open upper end and outwardly-projecting ears, of a pair of handle-bar arms pivoted to said ears and provided with worm-teeth at their inner ends, an operating-stem rotatably mounted in the casing and having a worm-thread that engages the teeth of the arms, said stem projecting above the open end of the casing and having an annular shoulder located within the casing, a retaining-ring secured in the upper end of the casing and bearing upon the annular shoulder of the stem, said ring having an outstanding flange at its upper end which projects over the upper end of the casing and a locking-ring secured upon the upper end of the casing and adapted to hold the clamping-ring against movement.

700,099. PROCESS OF TREATING SUGAR-CRYSTALS. GLAS A. BRONKHORST and CHARLES A. KISS, New York, N. Y., assignors to Federal Refining Company, Jersey City, N. J., a Corporation of New Jersey. Filed Nov. 19, 1900. Serial No. 62,857. (No specimens.)

Claim.—1. The method or process of refining or purifying a mass of sugar-crystals, consisting in washing the mass with a sulfurous de-aerating or cleaning agent which is a non-equivalent of sugar-crystals, and then separating the said agent together with the absorbed impurities, substantially as described.

2. The method or process of refining or purifying sugar-crystals, consisting in washing the mass with a sulfurous body, and then separating the said sulfurous body together with the absorbed impurities, substantially as described.

3. The method or process of refining or purifying sugar-crystals, consisting in washing the mass with a sulfurous body, and then separating from the mass the said sulfurous body together with the absorbed impurities, substantially as described.

4. The method or process of refining or purifying a mass containing sugar-crystals, consisting in washing the mass with a de-aerating or cleaning agent containing a sulfurous derivative of a sulfurous body, and then separating from the mass the said de-aerating or cleaning liquid together with the absorbed impurities, substantially as described.

700,100. SPARKING APPARATUS FOR GASOLINE-ENGINE. JOHN W. BRADY, Providence, R. I., assignor of one-half to Joseph D. Fitch, Providence, R. I. Filed Aug. 23, 1901. Serial No. 78,500. (No model.)

Claim.—1. In a sparking apparatus for a gasoline-engine, the combination of a properly-mounted oscillating shaft having a sparking-pin projecting therefrom, an electrode-bar mounted and longitudinally movable on a fixed support, means adapted to move said electrode longitudinally to the sparking-pin, and a spring adapted to be compressed by said longitudinal movement of the electrode and to move automatically the electrode longitudinally away from the sparking-pin when said spring is relieved from said compression, substantially as described.

2. In a sparking apparatus for a gasoline-engine, the combination of a properly-mounted oscillating shaft having a sparking-pin projecting therefrom, an electrode-bar mounted and longitudinally movable on a fixed support, a worm-bar secured to the electrode-bar at a right angle and movable therewith, a support on which said worm-bar is movable, and a spiral spring surrounding the electrode-bar and having one end bearing against said fixed support and the opposite end bearing against said worm-bar, substantially as set forth.

3. In a sparking apparatus for a gasoline-engine, the combination of a properly-mounted oscillating shaft having a sparking-pin projecting therefrom, an electrode-bar mounted and longitudinally movable on a fixed support, two parallel clamping-pieces adapted to embrace the outer end of the electrode-bar, two screw-threaded rods extending from a fixed cap-

port parallel with each other and with the electrode-bar, a thumb-screw engageable with each of said rods at the screw-threaded end thereof and having its inner end in contact with the edges of the clamping-pieces and a spiral spring surrounding the electrode-bar and having one end bearing against the first-named fixed support and the opposite end bearing against said clamping-pieces, substantially as specified.

4. In a sparking apparatus for a gasoline-engine, the combination of a properly-mounted oscillating shaft having a sparking-pin projecting therefrom, an electrode-bar mounted and longitudinally movable on a fixed support, two clamping-pieces adapted to embrace the outer end of the electrode-bar and each having two oppositely-extending arms, two screw-pieces passing through the adjacent arms of said clamping-pieces, as shown, two screw-threaded guide-rods extending from a fixed support parallel with each other and with said electrode-bar and in loose contact with the adjacent arms of the clamping-pieces respectively, a thumb-screw engageable with each of said guide-rods on the screw-threaded end thereof and having its inner end in contact with the edges of the clamping-pieces, and a spiral spring surrounding the electrode-bar and having one end bearing against the first-named fixed support and the opposite end bearing against said clamping-pieces, substantially as specified.

5. In a sparking apparatus for a gasoline-engine, the combination of a properly-mounted oscillating shaft having a sparking-pin projecting therefrom, an electrode-bar mounted and longitudinally movable on a fixed support, two clamping-pieces having joined a circular aperture wherein the outer end of the electrode-bar is movable, and each of which clamping-pieces has two oppositely-extending arms, two screws passing through the adjacent arms of said clamping-pieces, as shown, two screw-threaded guide-rods extending from a fixed support parallel with each other and with said electrode-bar and in loose contact with the adjacent arms of the clamping-pieces respectively, a thumb-screw engageable with each of said guide-rods on the screw-threaded end thereof and having its inner end in contact with the edges of the clamping-pieces, a spiral spring surrounding the electrode-bar and having one end bearing against the first-named fixed support and the opposite end bearing against said clamping-pieces, a screw-threaded spindle projecting axially from the outer end of the electrode-bar, and a thumb-screw engageable with said spindle and having its inner end in contact with said clamping-pieces, substantially as described.

6. The improved sparking apparatus for a gasoline-engine, consisting of the combination of a properly-mounted oscillating shaft having a sparking-pin projecting therefrom, a tubular barrel having a centrally-perforated partition in the bore thereof midway between its ends, a cylindrical bar mounted in said barrel and passing through said perforated partition, a packing surrounding a portion of said cylindrical bar within said barrel, a packing-ring in contact with the packing and loosely in contact with the cylindrical bar and having an annular flange covering the upper end of the barrel and projecting slightly beyond the edge thereof, screws passing through said annular flange into said barrel, an electrode mounted in the opposite end of the cylindrical bar and adapted to contact with the sparking-pin, a ring having an annular internal shoulder adapted to contact with the under side of the projecting portion of the flange of the packing-ring and provided with two diametrically opposite rounded bot-

two shouldered guide-rods inserted in said holes and having riveted ends therein and provided at their opposite ends with screw-threads, two clamping-pieces having when joined a circular aperture wherein the ends of the cylindrical bar is mounted and each of which clamping-pieces has two oppositely-extending-arms, between which respectively said two guide-rods loosely pass, two screws passing through the adjacent arms of the clamping-pieces, a screw-threaded spindle extending axially from the center end of the cylindrical bar, a thumb-screw engageable with said spindle, a thumb-screw engageable with the screw-threaded end of each of said guide-rods, and a spiral spring surrounding the cylindrical bar and having one end bearing against said packing-ring and the opposite end bearing against said clamping-pieces, substantially as shown and for the purpose specified.

700,101. APPARATUS FOR ANNEALING SILVER OR OTHER METALS. CALVIN STRIMMER, Newburyport, Mass., assignor to Twiss Manufacturing Company, Newburyport, Mass., a Corporation of Massachusetts. Filed July 1, 1901. Serial No. 64,696. (No model.)

Claim.—1. The combination of a muffle; means for heating the muffle exteriorly; a hot-gas-inlet pipe discharging into said muffle; a source of hot-gas supply connected with said hot-gas-inlet pipe; means for forcing said gas through said hot-gas-inlet pipe; a door for said muffle; a receiving-table at the front of said muffle; and a tank for an air-circulating bath; the receiving-table mounted to discharge into said tank.

2. The combination of a muffle; means for heating the muffle exteriorly; a hot-gas-inlet pipe discharging into said muffle; a source of hot-gas supply connected with said hot-gas-inlet pipe; means for forcing said gas through said hot-gas-inlet pipe; a receiving-table in front of said muffle, and near the door thereof; diverging supports for the table, and having steps at their front ends; transverse on opposite ends of the table; a chain attached to the table; a counterweight on the free end of the chain; a pulley over which the chain runs; the table being slidable on its supports between the muffle and said steps; and being tiltable when said to the front of said supports.

700,102. SELF-LEVELING WAGON. HERMAN W. THORPSON, Nigro, Ore. Filed Oct. 12, 1901. Serial No. 73,100. (No model.)

Claim.—A self-leveling wagon comprising a truck, bolsters supported thereon and provided with standards, axles or tracks securely fastened to the body of each bolster and the standards, a wagon-body, bottom brackets on said body provided with grooved and flanged rollers in engagement with the trucks, and side brackets on the wagon-body provided with grooved and flanged rollers also in engagement with the trucks, substantially as and for the purpose specified.

700,103. APPARATUS FOR THE STOPPAGE OF WATER FROM AUTOMATIC SPRINKLER HEADS AFTER FIRE OR ACCIDENT. THOMAS TITTON, Ashton-upon-Ribble, and EDWARD FLEMING, Preston, England, assignors to William Lewis Holland, Preston, England. Filed Feb. 12, 1902. Serial No. 65,000. (No model.)

Claim.—The combination with an automatic sprinkler installation, of an apparatus for closing a discharged sprinkler, said apparatus consisting, in its essential features, of a frame mounted upon a pole, a part con-

ried by the frame and arranged to engage the body of the sprinkler, a valvular part arranged to seal the sprinkler and operating means, each as a connected catch-hand-lever and retaining-pawl, substantially as and for the purpose herein set forth.

700,104. PAPER-FASTENER. HENRY THOMAS, JR., Brooklyn, N. Y. Filed Mar. 3, 1902. Serial No. 64,604. (No model.)

Claim.—An envelop-holder, comprising an eyelid adapted to be engaged through the back of an envelop, and fingers extended from opposite sides of the eyelid and adapted to be passed through the flap of the envelop and turned outward and down thereon, the material between the openings in the flap forming a cover or closure for the eyelid, substantially as specified.

700,105. VACUUM EVAPORATING APPARATUS. GERNARD E. VIL, Schürmühle, Switzerland. Filed Dec. 22, 1900. Serial No. 741,417. (No model.)

Claim.—1. In vacuum apparatus for obtaining salt from brine, the combination, with a pan provided with an internal system of heating-pipes and having its bottom constructed with a tubular extension, and a supply-reservoir arranged below said extension for receiving the mass and communicating with the atmosphere, of an air-pipe descending from the top of the pan, and a liquid seal for the lower end of said air-pipe, substantially as and for the purpose specified.

2. In vacuum apparatus for obtaining salt from brine the combination, with a pan provided with an internal system of heating-pipes and having its bottom constructed with a tubular extension for receiving the mass and communicating with the atmosphere, of an air-pipe descending from the top of the pan, a non-increasing liquid seal for the lower open end of said air-pipe, and means for preventing liquid from being drawn from said air-pipe into the pan, substantially as and for the purpose specified.

3. In vacuum apparatus for obtaining salt from brine the combination of a pan provided with an internal system of heating-pipes, and provided at the bottom with a tubular leg or extension, an open supply-tank below into which the said leg dips, an air-pipe communicating with the top of the pan and a liquid seal for the lower open end of said air-pipe; a removable double-legged "washing-pipe" one leg of which is adapted to be placed over the said tubular leg of the pan, and a cock-controlled brine-supply for the other leg of said double-legged pipe, substantially as and for the purpose hereinbefore set forth.

700,106. LOCK. RAIL WHITE and FRANK C. FREY, Baker City, Ore. Filed June 15, 1901. Serial No. 64,730. (No model.)

Claim.—1. The combination with a quadrant provided with a knob-bolt and a segmental cast, of an oscillating shackle having a key-slot and provided with a segmental tumbler to normally engage said cast, said tumbler having a shoulder and parallel openings having recesses and extending from the rear of said shoulder to the key-slot, pins of varying length movably mounted in said openings and provided with legs to work within said recesses, a stop-pin to limit the movement of said tumbler, and a dog to engage said shoulder to hold the tumbler normally in engagement with said cast, and having a segmental recess providing a shoulder to engage the inner projecting curved edge of said tumbler when a false key is inserted into the key-slot.

2. The combination with a casting, of a pivoted quadrant adapted to swing therein, provided with segmental slots 6 and 7, an oblong recess and a segmental cast, pins extending in said slots to limit the movement of the quadrant, an operating-lever working within the recess, a knob-bolt having a stem extending through an opening in the quadrant into the segmental slot 7, a pin holding said knob-bolt therein, an oscillating shackle having a key-slot and provided with a segmental tumbler to normally engage said cast, said tumbler having a shoulder and parallel openings having recesses and extending from the rear of said shoulder to the key-slot, pins of varying length movably mounted in said openings and provided with legs to work within said recesses, a stop-pin to limit the movement of said tumbler, and a dog to engage said shoulder to hold the tumbler normally in engagement with said cast, and having a segmental recess providing a shoulder to engage the inner projecting curved edge of said tumbler when a false key is inserted in the key-slot.

700,107. MANUFACTURE OF ELECTRIC CABLES. JULIAN E. WISE, Berlin, Germany. Filed Dec. 21, 1901. Serial No. 76,120. (No model.)

Claim.—1. In combination, a bulk of insulating material having notches in its sides and wires held in said notches, substantially as described.

2. In combination, a bulk of insulating material having notches in its sides or edges, wires in said notches and a cord to hold the wires in position, substantially as described.

3. In combination, a bulk of a continuous strip of insulating material having notches formed in its exterior and interior edges, and wires in said notches, substantially as described.

4. In combination, a bulk of insulating material having notches in its sides or edges arranged in a spiral line about the bulk and wires held in said notches, substantially as described.

5. In combination, a bulk of a flat strip of insulating material folded longitudinally, so as to form an upstanding edge having notches therein, wires in said notches and a cord to hold the wires therein, substantially as described.

6. In combination, a bulk of a flat strip of insulating material folded

longitudinally, so as to form an upstanding edge having notches in said edge, wires in said notches, the portions of the standing strip between the notches capable of being turned between the wires inward or from the center, substantially as described.

7. A bulk of a flat strip of insulating material having two longitudinal folds and both edges of the strip having notches, in combination with wires held in said notches, the parts between the notches on one edge of the strip projecting from the center and those on the other edge toward the center, substantially as described.

8. A bulk of a flat strip of insulating material folded longitudinally so as to be substantially Z shape in section and having notches in its edges, in combination with wires held in said notches, the parts between the notches of the strip on one edge projecting between the wires from the center of the bulk and those on the opposite edge projecting between the wires toward the center, substantially as described.

9. In combination, a bulk of a flat strip of paper folded longitudinally and notches cut from one edge of the strip to the line of fold and notches intermediate them of lesser depth, and wires held in said notches, substantially as described.

10. In combination, a bulk of a flat strip of paper having two parallel longitudinal folds and notches in each side of the strip from each edge to the adjacent longitudinal fold, the wires in said notches, the sides of the strip between the notches on one side projecting between wires and outward from the center of the bulk, and those on the other side projecting between wires toward the center of the bulk, substantially as described.

11. In combination, a bulk formed of a flat strip of paper having a longitudinal fold, and cross-shaped notches extending from one edge to said fold to form upstanding portions with lateral notches in said upstanding portions, substantially as described.

700,108. RAIL-CLAMP. ARTHUR H. WHITE, Gaylord, Mich. Filed Nov. 26, 1901. Serial No. 64,500. (No model.)

Claim.—A clamp of the class set forth comprising a member having a horizontal base-plate with an inwardly-extending side running above the same and continuing into a vertical element with an upper edge 7 constructed as a narrow tread-surface to lie flush with the upper surface of the heads of the rails to which the device is applied, a groove being formed between the inwardly-projecting portion of the side and the base-plate, the latter having handles at its opposite ends, a movable member hinged to the said handles and conforming in shape to the flange and recesses of the rails and of less vertical extent than the opposite right side, and bolts extending through the movable member and side and forming the sole means of movement of the clamp to the rails, the base-plate terminating at the point where the handles are formed.

700,109. COTTON-CHOPPER. WILLIAM R. WILKINSON, Glasgow, Ga. Filed Apr. 4, 1902. Serial No. 64,800. (No model.)

Claim.—1. In a cotton-chopper, a chopping-wheel comprising oppositely arranged and aligning disks having central circular recesses or cuts and oppositely-arranged radial knife-slots, a hub formed with annular flanges at the ends seated within the central circular recesses of the disks, a shaft in the hub, chopping-blades having their ends lodged in the radial slots of the disks, and driven about the disks over the ends of the knives, substantially as described.

2. In a cotton-chopper, a chopping-wheel comprising oppositely arranged and aligning disks having central circular recesses or cuts in the inner faces and oppositely-arranged radial knife-slots in their peripheral faces, a hub formed with annular flanges at the ends seated within the central circular recesses of the disks, bolts projected through the disks into the ends of the hub, a shaft in the hub, chopping-blades having their ends removably lodged in the radial slots in the disks, drive on the disks to hold the knives in position, and bolts through the drive and entering the disks to detachably hold the drive to the disks, substantially as described.

700,110. AUTOMATIC FEED APPARATUS. FRANK WERNER, Hamburg, Germany. Original application filed June 26, 1899, Serial No. 21,972. Divided and this application filed July 2, 1901. Serial No. 64,064. (No model.)

Claim.—1. An automatic regulating device comprising a pair of steam-lugs connected to an inlet-valve at one end and to an outlet-valve at the opposite end, said lugs adapted to diverge or expand, and converge or contract under varying temperatures, a spindle, means operated by the steam-lugs when displaced in one direction to rock said spindle in one direction, and means automatically rocking said spindle in a reverse direction on the displacement of the steam-lugs in a reverse direction, for the purpose set forth.

2. An automatic regulating device, comprising a pair of steam-lugs connected to an inlet-valve at one end and to an outlet-valve at the opposite end, said lugs adapted to diverge or expand and converge or contract under varying temperatures, a spindle, means operated by the steam-lugs when displaced in one direction to rock said spindle in one direction, and a weighted lever secured to said spindle to rock the same in a reverse direction, for the purpose set forth.

3. An automatic regulating device, comprising a pair of steam-lugs connected to an inlet-valve at one end and to an outlet-valve at the opposite end, said lugs adapted to diverge or expand and converge or contract under varying temperatures, a spindle, means operated by the steam-lugs when displaced in one direction to rock said spindle in one direction, and a two-armed lever having one of its arms weighted, said lever secured to the spindle to rock the same in a reverse direction, for the purpose set forth.

4. In an automatic boiler-feeding device, the combination with the feed-pipe, its valve and valve-stem; of a pair of steam-lugs connected at one end to a steam-inlet union and at the opposite end to a steam-outlet union, said steam-lugs adapted to diverge or expand and converge or contract under varying temperatures, means operated by the steam-lugs when displaced in one direction to rock the overhead valve-spindle in one direction and means automatically rocking said spindle in a reverse direction on the displacement of the steam-lugs in a reverse direction, for the purpose set forth.

5. In an automatic boiler-feed, the combination with the feed-pipe, its valve and valve-stem and a notched disk secured thereto; of a pair of steam-lugs connected to a steam-inlet union at one end and to a steam-outlet union at the opposite end, said lugs adapted to diverge or expand and converge or contract under varying temperatures, rods connected by the displacement of the steam-lugs in one direction and engaging the notches in the disk on the valve-spindle to rock the same in one direction, and means automatically rocking said spindle in a reverse direction on the displacement of the steam-lugs in a reverse direction, for the purpose set forth.

6. In an automatic boiler-feed, a pair of steam-lugs each composed of two tubes and an intermediate hollow union, said lugs connected at one end to a steam-inlet union and at the opposite end to a steam-outlet union, and a belt extending through each of the intermediate unions, said belts provided with recessed heads at their proximate ends; of a boiler-feed pipe, its valve and valve-stem, a weighted lever, and a disk secured to said stem, said disk having oppositely-arranged notches *p* and *q* and oppositely-arranged rods seated in the recesses in the heads of the above-said belts, the free beveled ends of said rods projecting into the notches *p*, *q*, respectively, substantially in and for the purpose set forth.

700,111. ELECTRICAL MEASURING INSTRUMENT. VITTORIO ARNONE, Spicchi, Italy, assignor to Cusella Olivetti, Ivrea, Italy. Filed July 18, 1899. Serial No. 20,725. (No model.)

Claim.—1. In an electrical measuring instrument, a movable part acted upon by the current, a counterbalancing device for equalizing the action of the current thereon, a shaft and means movable longitudinally of said shaft for automatically increasing and decreasing the tension of said counterbalancing device on said movable part.

2. In an electrical measuring instrument, a movable part acted upon by the current, a counterbalancing device for equalizing the action of the current thereon, a shaft and means movable longitudinally of said shaft and thrown into operation by an increase or decrease in the energy or other value of the current to be measured for increasing and decreasing the tension of said counterbalancing device on said movable part.

3. In an electrical measuring instrument, a movable part acted upon by the current, a counterbalancing device for equalizing the action of the current thereon, a shaft, means movable longitudinally of said shaft for automatically increasing and decreasing the tension of said counterbalancing device on said movable part, and means for indicating the force exerted on said counterbalancing device.

4. In an electrical measuring instrument, a movable part acted upon by the current, a counterbalancing device for equalizing the action of the current thereon, a shaft, means movable longitudinally of said shaft for automatically increasing and decreasing the tension of said counterbalancing device on said movable part, and means for continuously recording the force exerted on said counterbalancing device.

5. In an electrical measuring instrument, a movable part acted upon by the current, a counterbalancing device for equalizing the action of the current thereon, a shaft, means movable longitudinally of said shaft for automatically increasing and decreasing the tension of said counterbalancing device on said movable part, means for indicating the force exerted on said counterbalancing device, and means for continuously recording said force.

6. In an electrical measuring instrument, a movable part acted upon by the current, a counterbalancing device for equalizing the action of the current thereon, a motor, a rotary shaft operated thereby, a longitudinally-movable connecting device actuated by said shaft and attached to said counterbalancing device for increasing and decreasing the tension thereof, and means thrown into operation by said movable part for operating said motor in one direction or the other, according as the energy or other value of the current increases or decreases.

7. In an electrical measuring instrument, a movable part acted upon by the current, a counterbalancing device for equalizing the action of the current thereon, a motor, a rotary shaft operated thereby, a longitudinally-movable connecting device actuated by said shaft and attached to said counterbalancing device for increasing and decreasing the tension thereof, means thrown into operation by said movable part for operating said motor in one direction or the other, according as the energy or other value of the current increases or decreases, and an indicating device connected with said motor and operated thereby.

8. In an electrical measuring instrument, a movable part acted upon by the current, a counterbalancing device for equalizing the action of the current thereon, a motor, a rotary shaft operated thereby, a longitudinally-movable connecting device actuated by said shaft and attached to said counterbalancing device for increasing and decreasing the tension thereof, means thrown into operation by said movable part for operating said motor in one direction or the other, according as the energy or other value of the current increases or decreases, and a recording device connected with said motor and operated thereby.

9. In an electrical measuring instrument, a movable part acted upon by the current, a counterbalancing device for equalizing the action of the current thereon, a motor, a rotary shaft operated thereby, a longitudinally-movable connecting device actuated by said shaft and attached to said counterbalancing device for increasing and decreasing the tension thereof, means thrown into operation by said movable part for operating said motor in one direction or the other, according as the energy or other value of the current increases or decreases, an indicating device, and a recording device, both connected with said motor and operated thereby.

10. In an electrical measuring instrument, a movable part acted upon by the current, a counterbalancing device for equalizing the action of the current on said movable part, a motor for increasing and decreasing the tension of said counterbalancing device, a threaded shaft connected with

and operated by said motor, a threaded nut or collar on said shaft, movable longitudinally thereof and having said counterbalancing device connected with it, and means thrown into operation by said movable part for starting said motor in one direction or the other, according as the energy or other value of the current to be measured increases or decreases.

11. In an electrical measuring instrument, a movable part acted upon by the current, a counterbalancing device for equalizing the action of the current on said movable part, a motor for increasing and decreasing the tension of said counterbalancing device, a threaded shaft connected with and operated by said motor, a threaded nut or collar on said shaft, movable longitudinally thereof and having said counterbalancing device connected with it, means thrown into operation by said movable part for starting said motor in one direction or the other, according as the energy or other value of the current to be measured increases or decreases, and an indicating device connected with, and operated by, said shaft.

12. In an electrical measuring instrument, a movable part acted upon by the current, a counterbalancing device for equalizing the action of the current on said movable part, a motor for increasing and decreasing the tension of said counterbalancing device, a threaded shaft connected with, and operated by, said motor, a threaded nut or collar on said shaft, movable longitudinally thereof and having said counterbalancing device connected with it, means thrown into operation by said movable part for starting said motor in one direction or the other, according as the energy or other value of the current to be measured increases or decreases, and a recording device connected with, and operated by, said shaft.

13. In an electrical measuring instrument, a movable part acted upon by the current, a counterbalancing device for equalizing the action of the current on said movable part, a motor for increasing and decreasing the tension of said counterbalancing device, a threaded shaft connected with, and operated by, said motor, a threaded nut or collar on said shaft, movable longitudinally thereof and having said counterbalancing device connected with it, means thrown into operation by said movable part for starting said motor in one direction or the other, according as the energy or other value of the current to be measured increases or decreases, a worm secured to said shaft, a worm-wheel meshing therewith, and an indicating hand or pointer carried by said worm-wheel.

14. In an electrical measuring instrument, a movable part acted upon by the current, a counterbalancing device for equalizing the action of the current on said movable part, a motor for increasing and decreasing the tension of said counterbalancing device, a threaded shaft connected with, and operated by, said motor, a threaded nut or collar on said shaft, movable longitudinally thereof and having said counterbalancing device connected with it, means thrown into operation by said movable part for starting said motor in one direction or the other, according as the energy or other value of the current to be measured increases or decreases, a rotating drum or cylinder, and a marking device carried by said collar or nut and bearing against said drum.

15. In an electrical measuring instrument, a movable part acted upon by the current, a counterbalancing device for equalizing the action of the current on said movable part, a motor for increasing and decreasing the tension of said counterbalancing device, a threaded shaft connected with, and operated by, said motor, a threaded nut or collar on said shaft, movable longitudinally thereof and having said counterbalancing device connected with it, means thrown into operation by said movable part for starting said motor in one direction or the other, according as the energy or other value of the current to be measured increases or decreases, an indicating device, and a recording device, both connected with, and operated by, said shaft.

16. In an electrical measuring instrument, a movable part acted upon by the current, a spring connected thereto for overcoming the torque of the same and for maintaining said movable part normally at its zero-point, a shaft thrown into operation by an increase in the energy or other value of the current to be measured and longitudinally-movable means on said shaft for increasing and decreasing the tension of said spring.

17. In an electrical measuring instrument, a movable part acted upon by the current, a spring connected thereto for overcoming the torque of the same and for maintaining said movable part normally at its zero-point, a motor, a shaft operated thereby, means thrown into operation by said movable part for starting said motor in one direction or the other and means movable longitudinally of and by said shaft for increasing or decreasing the tension of said spring.

18. In an electrical measuring instrument, a movable part acted upon by the current, a counterbalancing device for equalizing the action of the current on said movable part, a reversible electric motor, a shaft operated thereby, a connecting device movable longitudinally of said shaft and attached to said counterbalancing device for increasing and decreasing the tension thereof, a circuit through said motor, and means thrown into operation by said movable part for closing the circuit through said motor in one direction or the other, according as the energy or other value of the current to be measured increases or decreases.

19. In an electrical measuring instrument, a movable part acted upon

by the current, a connecting rod or arm connected with said movable part and operated thereby, electric contacts between which said rod is mounted, a counterbalancing device for equalizing the action of the current on said movable part and thereby normally maintaining said movable part at its zero position and said rod at a point intermediate said contacts, a reversible electric motor, a shaft operated thereby, a connecting device movable longitudinally of said shaft and attached to said counterbalancing device for increasing and decreasing the tension thereof, a circuit through said motor adapted to be closed in one direction or the other by the engagement of said rod with one or the other of said contacts as the energy or other value of the current through the instrument increases or decreases.

20. In an electrical measuring instrument, a movable part acted upon by the current, a connecting rod or arm connected with said movable part and operated thereby, electric contacts between which said rod is mounted, a counterbalancing device for equalizing the action of the current on said movable part and thereby normally maintaining said movable part at its zero position and said rod at a point intermediate said contacts, a reversible electric motor, a shaft operated thereby, a connecting device movable longitudinally of and by said shaft and attached to said counterbalancing device for increasing and decreasing the tension thereof, a circuit through said motor adapted to be closed in one direction or the other by the engagement of said rod with one or the other of said contacts as the energy or other value of the current through the instrument increases or decreases, and indicating mechanism connected with, and operated by, said motor.

21. In an electrical measuring instrument, a movable part acted upon by the current, a connecting rod or arm connected with said movable part and operated thereby, electric contacts between which said rod is mounted, a counterbalancing device for equalizing the action of the current on said movable part and thereby normally maintaining said movable part at its zero position and said rod at a point intermediate said contacts, a reversible electric motor, a shaft operated thereby, a connecting device movable longitudinally of and by said shaft and attached to said counterbalancing device for increasing and decreasing the tension thereof, a circuit through said motor adapted to be closed in one direction or the other by the engagement of said rod with one or the other of said contacts as the energy or other value of the current through the instrument increases or decreases, and recording mechanism connected with, and operated by, said motor.

22. In an electrical measuring instrument, a movable part acted upon by the current, a connecting rod or bar connected therewith and operated thereby, contacts between which said rod is mounted, a counterbalancing device for equalizing the action of the current on said movable part and thereby normally maintaining said movable part at its zero-point and said rod at a point intermediate said contacts, a reversible electric motor for increasing and decreasing the tension of said counterbalancing device, a short-circuit from the line, including the field-magnets of said motor and two resistance-coils, circuit connections between said contacts and said short-circuit at points, respectively above and below said coils, and circuit connections between said connecting-rod, the armature of said motor, and said short-circuit, at a point intermediate said coils, whereby the circuit through said armature may be closed in one direction or the other by the engagement of said rod with one or the other of said contacts upon an increase or decrease in the energy or other value of the current through the instrument.

23. In an electrical measuring instrument, a movable part acted upon by the current, a connecting rod or bar connected therewith and operated thereby, contacts between which said rod is mounted, a counterbalancing device for equalizing the action of the current on said movable part and thereby normally maintaining said movable part at its zero-point and said rod at a point intermediate said contacts, a reversible electric motor for increasing and decreasing the tension of said counterbalancing device, a short-circuit from the line, including the field-magnets of said motor and two resistance-coils, circuit connections between said contacts and said short-circuit at points, respectively above and below said coils, circuit connections between said connecting-rod, the armature of said motor, and said short-circuit, at a point intermediate said coils, whereby the circuit through said armature may be closed in one direction or the other by the engagement of said rod with one or the other of said contacts upon an increase or decrease in the energy or other value of the current through the instrument, and indicating mechanism connected with and operated by said motor.

24. In an electrical measuring instrument, a movable part acted upon by the current, a connecting rod or bar connected therewith and operated thereby, contacts between which said rod is mounted, a counterbalancing device for equalizing the action of the current on said movable part and thereby normally maintaining said movable part at its zero-point and said rod at a point intermediate said contacts, a reversible electric motor for increasing and decreasing the tension of said counterbalancing device, a short-circuit from the line, including the field-magnets of said motor and

two resistance-coils, circuit connections between said contacts and said short-circuit at points respectively above and below said coils, circuit connections between said conducting-rod, the armature of said motor, and said short-circuit, at a point intermediate said coils, whereby the circuit through said armature may be closed in one direction or the other by the engagement of said rod with one or the other of said contacts upon an increase or decrease in the energy or other value of the current through the instrument, and recording mechanism connected with, and operated by, said motor.

700,112. CONTINUOUS HYDRO-EXTRACTOR. LEONARD ATWOOD, Philadelphia, Pa. Filed May 14, 1901. Serial No. 98,572. (No model.)

Claim.—1. A hydro-extractor having a perforated conical shell, a conical water-chamber within said shell and means for forcing water into the chamber and through perforations in the walls thereof, with a device in the lower portion of said shell for facilitating the removal of material therefrom after its liquid has been extracted, substantially as described.

2. A hydro-extractor having a casing, a perforated shell within the casing, a water-chamber within the shell having perforations in its walls and a device in the lower portion of the shell for facilitating the removal of material therefrom after its liquid has been extracted, substantially as described.

3. The combination in a conical perforated casing, means for revolving the same, said casing having an open bottom, a bladed wheel in the bottom, means for supplying material to the shell, a conical water-receptacle having a perforated body, and means for forcing water to said shell, substantially as described.

4. The combination in a conical perforated casing, of means for revolving the same, said casing having an open bottom, a bladed wheel in the bottom, means for supplying material to the shell, a conical water-receptacle having a perforated body, and means for forcing water to said shell, the body of said water-receptacle having inclined discharge-openings, substantially as described.

5. The combination in a conical perforated casing, means for revolving the same, said casing having an open bottom, a bladed wheel in the bottom, means for supplying material to said shell, a conical water-receptacle having a perforated body, and means for forcing water to said shell, the body of said water-receptacle having inclined discharge-openings, with a discharge-pipe at the bottom for discharging the material so that it will pass away from the machine, substantially as described.

700,113. CAN-OPENER. JAMES D. BROWN, Trinidad, Colo., assignor of one-half to William W. Griswold, Trinidad, Colo. Filed Oct. 24, 1901. Serial No. 78,830. (No model.)

Claim.—1. A can-opener having an approximately cylindrical upwardly-tapered or reduced blade provided with cutting edges which progress spirally in opposite directions from a penetrating-point, to cause the transverse compression of the several portions of a can-top as the blade advances therethrough.

2. A can-opener having an approximately cylindrical, transversely-expandable blade, reduced in diameter toward its tip, and having spirally-disposed downwardly-convergent cutting edges intersecting to form a penetrating-point.

3. A can-opener having an approximately cylindrical, transversely-expandable blade provided with spirally-disposed downwardly-convergent cutting edges intersecting to form a penetrating-point, and a handle secured to the upper edge of the blade at one point and provided with a brace having a plurality of bearings on the edge of the blade to provide for the application of downward pressure to the blade without interfering with transverse expansion.

4. A can-opener having an approximately cylindrical, transversely-expandable, upwardly-reduced or tapered blade, of which the cutting edges progress spirally from a penetrating-point and terminate short of each other near the upper edge of the blade, and a handle secured to the blade at its upper edge and remote from the terminus of the cutting edges and provided with a brace or cross-head bearing on the upper edge of the blade adjacent to said terminus of the cutting edges.

700,114. GUN-CARRIAGE. KARL DUMMER, Ploem, Austria-Hungary, assignor to The Firm of Steudacher, Aktiengesellschaft in Ploem, Ploem, Austria-Hungary. Filed Dec. 26, 1901. Serial No. 77,269. (No model.)

Claim.—1. In a gun-carriage, the combination with the trail thereof, of a spade detachably connected thereto, a spring-pressed rod suitably connected with the trail, means for connecting the said rod with the spade, said means provided with projections, guides attached to the trail for the said projections when the spade is retracted, and means carried by the trail to prevent the dropping down of the spade.

2. In a gun-carriage, the combination with the trail of a spade adapted to operate between the sides of the trail, a pin removably secured to the trail for detachably and pivotally connecting the spade thereto, a spring-pressed rod, a bearing connected with the trail for supporting one end of the rod, a bolt provided with projections, said bolt adapted to connect the other end of the rod to the spade, curved-shaped guides carried by the trail for the said projections when the spade is retracted, and means on the trail to prevent the dropping down of said spade and rod.

700,115. BURNING APPARATUS. JOHN BELL, White, N. H. Filed Sept. 18, 1901. Serial No. 78,888. (No model.)

Claim.—1. In a burning apparatus, the combination with a platform of parallel tilting beams connected at their front ends by a trans-

verse bar, journals secured to the tilting beams, means for tilting said beams, and means for guiding them in their movement, comprising bars having curved slots adapted to receive the said journals.

2. In a burning apparatus, the combination with a fixed platform of parallel tilting beams connected at their front ends by a transverse bar, said bar having its ends projecting beyond the tilting beams, means for tilting said beams, and guides secured to the frame adapted to receive the projecting ends of the said transverse bar.

3. In a burning apparatus, the combination with a platform having keeplines secured to its under side, of a pair of tilting beams, means for raising and lowering the same, and means for locking the tilting beams in position comprising a locking-bar slidably mounted in the said keeplines, a horizontally-disposed lever fulcrumed below the platform, strips connecting the said locking-bar to one end of the said lever, and a vertically-disposed lever fulcrumed on the frame having its lower end connected to the opposite end of the horizontally-disposed lever.

4. In a burning apparatus, the combination with a fixed platform of parallel tilting beams connected at their front ends by a transverse bar, means for tilting said beams and means for guiding them in their movement, comprising transversely-inclined bars having curved slots and projections from said transverse bar moving in said slots.

5. In a burning apparatus, the combination with a pair of weighted tilting beams, of a transverse beam connecting the front ends of the beams, journals projecting from the ends of said beam, pulleys on said journals, elevating-cords on said pulleys, inclined bars rising from the frame and having curved slots to receive the ends of said journals, a winding-shaft and crank for said cords, means for locking the beams against movement, a conveyor and a chute adjacent to the conveyor.

700,116. HITCHER-BLOCK AND LEVER CONNECTION. CHARLES F. FAZ, Chicago, Pa., assignor to J. Stevens Arms & Tool Company, Chicago, Pa., Inc., a Corporation. Filed July 25, 1901. Serial No. 68,219. (No model.)

Claim.—1. The combination in a breech-loading firearm of a breech-block pivotally supported therein and adapted to swing in the plane of the base of the arm, a thumb-lever for operating the block, and means for rigidly connecting the lever to the block consisting of a sleeve, lugs thereon for engaging recesses in the breech-block and in the side of the thumb-lever, and a screw-threaded pin loose in the sleeve and having a threaded engagement with the breech-block, substantially as described.

2. The combination in a breech-loading firearm, of a breech-block pivotally supported therein adapted to swing in the plane of the base of the arm, said block having a vertically-located slot therein, an extractor in said slot, a thumb-lever for operating the block, and means for rigidly connecting the lever to the block and for supporting said extractor, consisting of a sleeve, lugs thereon for engaging recesses in the breech-block and in the side of the thumb-lever, and a screw-threaded pin loose in the sleeve and having a threaded engagement with said breech-block and extractor, substantially as described.

700,117. TYPE-WRITER COPY-HOLDER. FRANK E. GRAY, Franklin, Pa. Filed Dec. 24, 1900. Serial No. 68,967. (No model.)

Claim.—1. In a type-writer copy-holder, the combination with a base having a standard, of a substantially horizontal arm slidably mounted upon the upper end of the standard and having a downwardly-curved pin at its outer end, a stop located upon the depending end of the pin, a bracket carrying a rack, said bracket being slidably and reversibly mounted upon the pin, and means for maintaining the bracket at any desired position upon said pin.

2. In a type-writer copy-holder, the combination with a base, of an upright sectional adjustable standard, one section of which is secured to the base, and another section is slidably mounted upon said base-section, a horizontally-disposed arm slidably mounted upon the upper end of the standard and provided with a downwardly-curved depending pin having an enlarged head, a bracket reversibly and slidably mounted upon the pin and bearing upon the enlarged head, said bracket having its outer face inclined, and a copy-holding rack secured to said inclined face.

700,118. PIPE OR TUBE SAWING MACHINE. HENRY W. HATTON, Mason City, Iowa. Filed May 2, 1901. Serial No. 68,662. (No model.)

Claim.—A tube-sawing machine comprising a cylindrical and revolvable body, an eccentric bearing rotatably mounted in the body, a revolvable mandrel mounted eccentrically within the bearing, means for revolving the body, bearing and mandrel independently of each other, a rack upon the bearing, a pin upon the body adapted to engage the rack, and a saw upon the mandrel, and a spring secured to the body and adapted to press the saw against the tube to be cut and hold the body in operative position.

700,119. PRINTING-PRESS. ROBERT HENSON, Baltimore, Md., assignor to the Duplex Printing Press Co., Baltimore, Md. Filed July 19, 1901. Serial No. 68,681. (No model.)

Claim.—1. The combination of a cylinder, in gear, a bed consisting with the cylinder and a bed-car mounting with said gear, the teeth of the rack being irregular to permit play of the cylinder relatively to the rack while on impression, substantially as described.

2. The combination of a cylinder and bed, the cylinder-gear, and the bed-rack consisting with said gear, said rack having its intermediate teeth thinner than its end teeth, and the spaces therebetween correspondingly wider, for the purpose and substantially as described.

3. The combination of a cylinder and bed, the gear on the cylinder and a bed-rack mounting thereon having its teeth opposite the type-

flaps on the head reduced in thickness, and the space therebetween increased to permit play of the cylinder relatively to the gear while on impression, the teeth of the rack beyond the flange increasing to fill also to correct any lost motion or accelerated movement of the cylinder during impression, substantially as and for the purpose set forth.

700,120. PHOTOGRAPH-ROLL HOLDER. DAVID E. HOSMER, Hunter, N. D. Filed Mar. 12, 1897. Serial No. 67,994. (No model.)

Claim.—1. In a photograph-roll holder the combination of a casing having a front opening, a slide in said front opening, a film-support having two of its edges connected to the outside walls of said casing, said film-support having an observation-aperture therethrough, rounded guides for the film positioned in line with the said film-support, winding and supply chambers located in the rear of said film-support, winding and supply spools pivoted in said chambers, and a winding device adapted to turn the reel-spools, the casing being arranged to open and allow access to the interior thereof.

2. In a photograph-roll holder the combination of a casing having a front opening, a slide in said front opening, rounded film-guides positioned in the right and left interior front corners of the casing, a film-support provided with an observation-aperture therethrough, said film-support positioned in line between the rounded film-guides, the film-support having two of its edges connected to the interior parts of the outside walls of the casing, the casing having a central compartment open at its rear side, through which central compartment observation can be had through the observation-aperture in the film-support, two closed side compartments, said side compartments formed by walls connected to the film-support on opposite sides of the observation-aperture and by walls forming the outer sides of the casing, a spool located in one of said side compartments, a reel located in the other of said side compartments, and a reel-winding device passing through a wall of the casing, the casing being arranged to open and allow access to the interior thereof.

3. In a photograph-roll holder the combination of a casing constructed with a film-support connected to the interior parts of two of its outside walls, said casing having a front opening, a slide in said front opening, a central compartment having the opening at its rear side, and being located between two side compartments, said central compartment having its front wall formed by the film-support, said front wall of the central compartment having an observation-aperture therethrough, two side compartments formed by the outside walls of the casing and the film-support and the side walls of the central compartment, a reel-winding device passing through a wall of the casing, the casing being arranged to open and allow access to the interior thereof.

700,121. EYELET. BRADSHAW KIMBALL, Boston, Mass., assignor to United Fastener Eyelet Company, Portland, Me., and Boston, Mass., a Corporation of Maine. Filed Jan. 20, 1898. Serial No. 71,498. (No model.)

Claim.—1. An eyelet comprising a tubular body and a cap of fabric and celluloid at one end thereof.

2. An eyelet having a head, and a cap or flange on said head, said cap or flange consisting of fibrous material combined with plastic material.

3. An eyelet comprising a tubular metal body and a fabric sheath secured thereon by means of celluloid, said fabric being also fixed by celluloid.

4. An eyelet comprising a tubular body having a flaring end, and a cap protecting said end and consisting of a fabric sheath fixed with wear-resisting material.

5. An eyelet comprising a tubular metal body, a molded ring of celluloid thereon, and a fabric sheathing-ring within the celluloid and covering the edge of the metal.

6. An eyelet comprising a tubular body having a flaring end, and a cap molded upon said flaring end, said cap consisting of wear-resisting material in which fabric is embedded.

7. A metal eyelet having a head, and a cap secured upon said head and consisting of fibrous material fixed with wear-resisting material.

8. An eyelet comprising a tubular body having a flaring end, and a cap upon said end, said cap consisting of compressed celluloid in which fabric is embedded, and being of larger diameter than said flaring end.

9. An eyelet comprising a tubular body having a flaring end, and a

single-ply sheath of fabric fixed with celluloid and keyed upon and protecting said flaring end.

10. An eyelet comprising a tubular body having a flaring end, and an annulus of fabric and celluloid protecting said flaring end, the celluloid being said fabric and also forming a flange around and beneath said flaring end.

11. An eyelet comprising a metallic body having an enlarged end, and an annulus of fabric having a thin flange of celluloid and protecting said end, the annulus and the celluloid forming a flange of greater diameter than said enlarged end, and interlocking therewith.

12. An eyelet comprising a metal body having a head, and a cap of celluloid compressed upon and including said head; said cap having a reinforcement of fibrous material embedded therein.

13. An eyelet comprising a tubular body and a flaring end, and a thin cap of celluloid compressed upon and including said flaring end; said cap having a rounded top surface and a plane outer surface, and also having an internal reinforcement of fibrous material which sheaths said flaring end.

14. An eyelet comprising a tubular body and a flaring end, and a cap upon said end, said cap comprising an annular sheath of fibrous material embedded in celluloid, the diameter of said sheath being greater than that of said flaring end.

15. An eyelet having a tubular metal body provided with a flange or enlargement at its outer end, and also having a rigid wear-resisting covering including and interlocked with the flange or enlargement and forming on the outside of the eyelet a shoulder adapted to bear on the material in which the eyelet is inserted; and an annulus of fabric embedded within said covering and overlying the outer edge of said tubular body.

16. An eyelet having a lateral flange or ledge upon its outer end, and a cap made of plastic material surrounding and including said flange, said cap being made with a central locking-portion, a rounded outer surface, and a shoulder surrounding said tubular part beneath said flange and arranged substantially at right angles to the axis of the eyelet, the lower end of the tubular body being adapted to be clamped against the under surface of the material to which the eyelet is applied, and cooperating with said shoulder in securing the eyelet to said material, and an annulus of reinforcing fabric being embedded in said plastic material.

17. An eyelet comprising a tubular metallic body having at the top an outwardly-extending flange and a cap or covering of plastic material surrounding and including said flange, and formed on the under side of said flange with a shoulder arranged substantially at right angles to the axis of the eyelet, an annulus of reinforcing fabric being embedded in said cap and overlying said flange.

18. An eyelet having a tubular metal body provided with a flange or enlargement at its outer end, and also having a rigid wear-resisting covering including and interlocked with the flange or enlargement and forming on the outside of the eyelet a shoulder adapted to bear on the material in which the eyelet is inserted; and an annulus of fabric embedded within said covering and overlying the outer edge of said tubular body, said fabric being in direct contact with the edge of the said flaring portion.

700,122. LACING-BOOK. BRADSHAW KIMBALL, Boston, Mass., assignor to Sidney W. Winslow, trustee, Beverly, Mass. Filed Jan. 20, 1898. Serial No. 71,515. (No model.)

Claim.—1. A lacing-book having a head and a cap or flange on said head, said cap or flange consisting of fabric and celluloid.

2. A lacing-book having a head, and a cap or flange on said head, said cap or flange consisting of fibrous material combined with plastic material.

3. A lacing-book having a head, and a fabric sheath secured upon said head by means of celluloid, said fabric being also fixed by celluloid.

4. A lacing-book comprising a metal body, a head, and a cap molded upon said head and consisting of celluloid and fabric, the fabric forming a sheath within the celluloid and covering the edge of the metal in the head.

5. A lacing-book comprising a body and a head, and a cap protecting said head and consisting of a fabric sheath fixed with wear-resisting material and compressed upon said head.

6. A lacing-book having a metal head, and a cap secured thereon and consisting of fibrous material fixed with wear-resisting material.

7. A lacing-book having a head and fabric protecting said head, said fabric having a thin flange of celluloid, and the fabric and celluloid interlocking and interlocking with the edge of said head.

8. A lacing-book having a head and a cap molded thereon, said cap consisting of celluloid in which a sheath of fabric is embedded, and the spread of said sheath being greater than that of said head.

9. A lacing-book having a metal head, a rigid wear-resisting covering including and interlocking with said head, and a portion of fabric embedded within said covering and serving as a sheath for the edge of said head.

700,128. PLAYING-BALL. BRADSHAW KIMBALL, Boston, Mass., assignor to The Kimball Manufacturing Company, a Corporation of New Jersey. Filed Mar. 27, 1898. Serial No. 100,587. (No model.)

Claim.—1. A playing-ball comprising a shell which consists of laminae of gutta-percha and fibrous material in alternation.

2. A playing-ball comprising a springy core and a shell thereon consisting of laminae of gutta-percha and laminae of fabric alternating with the gutta-percha laminae.

3. A playing-ball comprising a springy core and a shell holding the same under compression and consisting of laminae of fabric and laminae of gutta-percha in alternation.

4. A playing-ball comprising a springy core and a shell thereon consisting of five laminae of gutta-percha and four laminae of fabric alternating with the gutta-percha laminae.

5. A playing-ball comprising a springy core and a shell thereon consisting of laminae of gutta-percha and laminae of cloth of open mesh alternating with said gutta-percha laminae; said laminae being interlocked.

6. A playing-ball comprising a springy core and a shell consisting of laminae of gutta-percha and laminae of cloth of open mesh alternating with said gutta-percha laminae, said laminae being interlocked, and said core being held under compression by said shell.

700,124. PLAYING-BALL. BRADSHAW KIMBALL, Boston, Mass., assignor to The Kimball Manufacturing Company, a Corporation of New Jersey. Filed Apr. 4, 1898. Serial No. 101,498. (No model.)

Claim.—1. A playing-ball having a cloth cover, the ball comprising spherical segments of plastic material joined together, and the cover having internal portions which are locked between the segments.

2. A ball having a cloth cover, the ball comprising spherical segments of gutta-percha welded together, and the cover having internal portions which are locked between said segments.

3. A playing-ball having a cloth cover, the ball comprising a core and hemispherical segments of plastic material welded together upon said core and holding the same under compression, and the cover having internal portions which are locked between said segments.

4. A ball having a cloth cover, the ball comprising a sphere or core of soft rubber and hemispherical segments of gutta-percha welded together upon said core and holding the same under compression, and the cover having internal portions which are locked between said segments.

5. A playing-ball having a cloth cover made in sections, the ball comprising spherical segments of plastic material welded together, each of said segments having one of the cover-sections, and the latter having internal portions or brims which are locked between said segments.

700,125. SPINNING-ROLL. BRADSHAW KIMBALL, Boston, Mass. Filed Apr. 18, 1898. Serial No. 100,541. (No model.)

Claim.—1. A roll consisting of a core, a layer of soft rubber thereon, and a shell upon said soft rubber consisting of celluloid in which fibrous

material is embedded, said shell holding said soft rubber under compression.

2. A roll consisting of a core, a layer of soft rubber cemented thereon, and a compound layer forming a shell upon said soft rubber; said shell consisting of woven fabric and celluloid and holding said soft rubber under compression.

3. A roll consisting of a core, a layer of soft rubber cemented thereon, and a compound layer forming a shell upon said soft rubber; said shell consisting of woven fabric and celluloid, the latter forming the periphery of the roll, said shell holding said soft rubber under compression.

4. A roll consisting of a core, a layer of yielding material thereon, and a hard shell holding said yielding layer under compression.

5. A roll consisting of a core, a layer of yielding material thereon, and a hard shell of waterproof material holding said yielding layer under compression.

6. A roll consisting of a core, a layer of soft rubber thereon, and a shell holding said soft-rubber layer under compression; said shell consisting of waterproof plastic material compounded with fabric.

7. A roll comprising a core, a soft-rubber layer thereon, a layer of fabric, provided with a flange of celluloid, holding said rubber layer under compression.

8. A roll comprising a core, a soft-rubber layer thereon, and a shell holding said rubber under compression; said shell comprising a layer of woven fabric and a flange of celluloid.

9. A roll comprising a core, a layer of soft rubber thereon, and a shell consisting of a sheet of celluloid having fabric embedded therein and wrapped around said soft rubber and welded together at its edges; said shell holding said soft rubber under compression.

700,126. SYSTEM OF ELECTRIC RAILWAYS OF THE SECTIONAL TYPE OF CONDUCTORS OR RAILS. CHARLES J. KENTNER, New York, N. Y. Filed Dec. 2, 1891. Serial No. 84,388. (No model.)

Claim.—1. The described method of avoiding collisions between cars passing over an electric railway having a working course of current-supply and a sectional system of normally dead working conductors, consisting in causing the moving cars to automatically break the sectional working conductors into connection with the working course of current-supply

in sequence as they pass over the route, and to automatically release said conductors in like sequence as the ends of the adjoining sectional conductors are passed, simultaneously utilizing a part of the working current taken directly from a live section over or by which a car is passing to continuously prevent any circuit connection whatever between a sectional conductor immediately in the rear of the live section and the current feeder or main, until the car has passed out of the section on which it is located.

2. The described method of avoiding collisions between cars passing in opposite directions over an electric railway having a working source of current-supply and a sectional system of normally dead working conductors; consisting in causing the moving cars to automatically lock the sectional working conductors into connection with the working source of current-supply in sequence as they pass over the route, and to automatically release said conductors in like sequence as the ends of the adjoining sectional conductors are passed; simultaneously utilizing a part of the working current to prevent the sectional conductors immediately in the rear and in the advance of any car from being connected to the working source of current-supply until said car has passed out of the section on which it is located.

3. The described method of avoiding collisions between cars passing over an electric railway having a working source of current-supply and a sectional system of normally dead working conductors, consisting in maintaining each sectional conductor in electrical connection with the working source of current-supply, while a car is passing over or by it, by a local source of applied power or energy independent of or distinct from the working source of current-supply; releasing said conductors in sequence as the car passes out of the successive sections and simultaneously utilizing a part of the working current taken directly from a live section over or by which a car is passing to continuously prevent any circuit connection whatever between a sectional conductor immediately in the rear of the live section and the current feeder or main, until the car has passed out of the section on which it is located.

4. The described method of avoiding collisions between cars passing over an electric railway having a working source of current-supply and a sectional system of normally dead working conductors; consisting in maintaining each sectional conductor in electrical connection with a working source of current-supply while a car is passing over or by it by a local source of applied power or energy independent of or distinct from the working source of current-supply; successively releasing said conductors through the agency of a part of the working current taken directly from a live section over or by which a car is passing and continuously utilizing the same to prevent any circuit connection whatever between a sectional conductor adjacent to the live section and the current feeder or main until the car has passed out of the section on which it is traveling.

5. The described method of preventing front or rear end collisions upon an electric railway having a working source of current-supply located at a power-house and a sectional system of normally dead working conductors extending over the route; consisting in maintaining each sectional conductor in electrical connection with the working source of current-supply while a car is passing over or by it, through the agency of an applied power or energy, independent of or distinct from the working current; releasing or disconnecting said sectional conductors from the working source of current-supply in sequence and simultaneously utilizing a part of the working current for preventing the adjacent sectional conductors in the rear and advance of any sectional conductor thus made alive from being connected to the working source of current-supply.

6. The described method of avoiding collisions between cars passing over an electric railway having a working source of current-supply and a sectional system of normally dead sectional conductors; consisting in causing the cars to connect the sectional conductors to the current feeder or main as they pass over the same, maintaining said connection by a source of locally-applied power or energy, independent of or distinct from the working source of current-supply; successively releasing said conductors through the agency of a part of the working current taken directly from a live section over or by which a car is passing and continuously utilizing the same to prevent any circuit connection whatever between a sectional conductor adjacent to the live section and the current feeder or main until the car has passed out of the section on which it is traveling.

700,127. ELECTRIC RAILWAY. CHARLES J. KENTNER, New York, N. Y. Original application filed May 4, 1901, Serial No. 53,992. Divided and this application filed Mar. 20, 1902. Serial No. 59,141. (No model.)

Claim.—1. In a system of electric railways of the sectional-conductor type the method of preventing abnormal or damaging arcing at the terminals of the switches where the sectional conductors are connected to and disconnected from the current feeder or main; consisting in automatically reducing the current-flow delivered through the terminals by successive steps until a current is flowing to an amount insufficient to

damage the same at the time that the sectional conductor is disconnected from the feeder or main.

2. In a system of electric railways of the sectional-conductor type the method of preventing abnormal or damaging arcing at the terminals of the switches where the sectional conductors are connected to and disconnected from the current feeder or main; consisting in automatically increasing the resistance to the current delivered through the terminals by successive steps until a current is flowing to an amount insufficient to damage the same at the time that the sectional conductor is disconnected from the feeder or main.

3. In a system of electric railways of the sectional-conductor type the method of preventing abnormal or damaging arcing at the terminals of the switches where the sectional conductors are connected to and disconnected from the current feeder or main, and damage to the current-collector and translating device carried by a car; consisting in automatically reducing the current-flow through the terminals and to the translating device as the current-collector passes from one sectional conductor to another and correspondingly increasing the current-flow as it advances upon the next adjacent sectional conductor.

4. In a system of electric railways of the sectional-conductor type the method of preventing abnormal or damaging arcing at the terminals of the switches where the sectional conductors are connected to and disconnected from the current feeder or main, and damage to the current-collector and translating device carried by a car; consisting in automatically increasing the resistance to the current delivered through the terminals and at the ends of adjacent sectional conductors as the current-collector passes from one sectional conductor to another, and in correspondingly decreasing the resistance to the current-flow as it advances upon the next adjacent sectional conductor.

700,128. ELECTRIC RAILWAY. CHARLES J. KENTNER, New York, N. Y. Filed May 4, 1901. Serial No. 53,992. (No model.)

Claim.—1. A safety system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and switching mechanism for connecting said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with safety-circuits including devices for releasing the conducting-terminals of the switches, said safety-circuits being permanently connected to the negative pole of the power-house generator so as to be normally without electrical current potential; the entire arrangement being such that when a car is passing by or over a given sectional third rail or conductor the switch at the distant end of the sectional third rail or conductor immediately in the rear thereof is rendered temporarily inoperative until the car passes out of said section, substantially as described.

2. A safety system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and switching mechanism for locking said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with safety-circuits, two for each sectional third rail or conductor, said safety-circuits including devices for releasing the conducting-terminals of the switches and so connected to the power-house generator as to be normally without electrical current potential, the entire arrangement being such that when a car is passing by or over a given sectional third rail or conductor the switches at the distant ends of the two

adjacent sectional third rails or conductors are both rendered temporarily inoperative until the car passes out of the section over which it is traveling, substantially as described.

3. A safety system of electric railways, embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and switching mechanism having conducting-terminals for connecting said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with releasing-electromagnets for the conducting-terminals of the switches, the individual coils of said releasing-magnets being included in circuit with safety-circuits running in opposite directions and connected to earth and to the adjacent ends of distant sectional third rails or conductors, substantially as described.

4. A system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom, and a series of electromagnetic switching devices for connecting said sectional conductors to the current feeder or main as a car passes by or over the same; in combination with additional conductors, two for each sectional third rail or conductor, said additional conductors including electromagnetic devices for releasing the conducting-terminals of the switches, the entire arrangement being such that when a car is passing by or over a given sectional third rail or conductor the switches at the distant ends of the two adjacent sectional third rails or conductors are both rendered temporarily inoperative until the car passes out of the section over which it is traveling, substantially as described.

5. A system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and electromagnetic switching devices having conducting-terminals for connecting said sectional conductors to the current feeder or main as a car passes by or over the same; in combination with releasing-electromagnets for disconnecting the terminals of the switches, the individual coils of said releasing-magnets being included in circuit with conductors running in opposite directions and connected to earth and to the adjacent ends of distant sectional third rails or conductors, substantially as described.

6. An electric-railway system embracing a current feeder or main; a series of sectional third rails or conductors for a main track normally disconnected from the current feeder or main and a siding having a third rail or conductor adapted to be connected in circuit with the current feeder or main; in combination with switching devices and circuit connections whereby when a car approaches within a definite distance of the siding it obtains control of the operating-current for a section of the main track until it passes upon the siding adjacent thereto; together with additional means for restoring the circuit condition of the sectional conductor of the main track to normal, the arrangement being such that no other car can approach the siding in either direction until the first-named car has been side-tracked and the circuits restored to normal condition, substantially as described.

7. An electric-railway system embracing a current feeder or main; a series of sectional third rails or conductors for a main track normally disconnected from the current feeder or main and a siding having a third

rail or conductor adapted to be connected in circuit with the current feeder or main; in combination with switching devices so arranged that when a car approaches within a definite distance of the siding it obtains control of the working current for the section adjacent to the siding and in such manner that no car can approach in either direction until the first-named car has passed upon the siding, substantially as described.

8. In an electric-railway system a current feeder or main, two or more sectional third rails or conductors normally disconnected therefrom and switching mechanism adapted to connect said sectional conductors to and disconnect them from the current feeder or main as a car passes over the route; together with a siding and circuit connections therefor so arranged that when a car passes within a definite distance of the siding it obtains absolute control of the working current for that section until said car has passed upon the siding; and additional means for restoring the electrical condition of the third rails of the main track to normal after the car has been properly side-tracked, substantially as described.

9. A safety system of electric railways embracing a current feeder or main; a series of sectional third rails or conductors normally disconnected therefrom and switching mechanism for connecting said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with a drawbridge carrying a sectional third rail or conductor and circuit and circuit connections relatively so arranged with relation to one of the first-named sectional third rails or conductors that when the drawbridge is moved from its normal or closed position a car is prevented from approaching either end thereof, substantially as described.

10. A safety system of electric railways embracing a current feeder or main; a series of sectional third rails or conductors normally disconnected therefrom and switching mechanism for connecting said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with a drawbridge carrying a sectional third rail or conductor and circuit and circuit connections relatively so arranged with relation to one of the first-named sectional third rails or conductors that when the drawbridge is moved from its normal or closed position no working current can be supplied to an approaching car for a definite distance from either end of the bridge, substantially as described.

11. A safety system of electric railways embracing a current feeder or main; a series of sectional third rails or conductors normally disconnected therefrom and switching mechanism for connecting said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with a drawbridge carrying a sectional third rail or conductor, circuit and circuit connections and locking mechanism, all so arranged that when a car approaches either end of said bridge within a definite distance the latter is locked or held so that it cannot be disturbed until after the car has crossed the bridge or passed out of the section which includes the bridge, substantially as described.

12. In a safety system of electric railways a current feeder or main; a series of sectional third rails or conductors normally disconnected therefrom; switching devices for connecting said sectional conductors to and disconnecting them from the current feeder or main as a car or vehicle passes over the route; in combination with a similar system crossing the first-named system; together with switching devices, circuit and circuit connections for both systems, so arranged that when a car reaches a definite point from the crossing in either direction it prevents any other car, approaching in any direction or either of the four intersecting branches, from advancing toward the crossing beyond a definite distance until the first-named car has crossed, substantially as described.

13. Two systems of electric railways embracing each a current feeder or main; a series of sectional third rails or conductors normally disconnected therefrom; switching devices for connecting said sectional third rails or conductors to and disconnecting them from the current feeder or main; in combination with electrical circuits and circuit connections for the two systems so interconnected and arranged that when a car reaches a definite point from the crossing in either direction it obtains absolute control of the working current of both systems and prevents any car from approaching the crossing upon any of the four intersecting branches by depriving it of working current at definite points from the crossing until the first-named car has crossed, substantially as described.

14. A system of electric railways of the sectional-third-rail type embracing a current feeder or main and switching devices for connecting the third-rail sections to the current feeder or main; in combination with circuit-closing rails or contacts located at the adjoining ends of the sectional third rails or conductors and on opposite sides thereof; together with a reversible trolley, the arrangement being such that the sectional third rails are connected to the current feeder or main in advance of the trolley so matter in which direction the latter may be moving, substantially as described.

15. In a sectional-third-rail system of electric railways a series of switches; in combination with a series of sectional third rails or conductors and a series of water-tight switch-boxes including electromagnetic switching mechanism; together with a current feeder or main, all of said

parts being supported or retained by said insulators, the switch-beams being constructed of insulating material and each provided with an opening at its bottom through which all of the circuit connections are effected, together with a removable water-tight cover adapted to prevent the admission of water after the manner of a diving-bell, substantially as described.

15. Means for preventing arcing at the ends of adjacent sectional third-rail sections of a third-rail system of electric railways and at the terminals in the switch-beams thereof, consisting of a variable resistance and circuit connections so arranged that as a car approaches the adjacent ends of two third rails the current supplied to the motor is reduced to a minimum and again restored to normal conditions after the switch is operated, substantially as described.

17. An electric-railway system embracing a current feeder or main; a series of sectional third rails or conductors normally disconnected therefrom; switching devices for connecting said sectional third rails or conductors to and disconnecting them from the current feeder or main; in combination with a car provided with a trolley or contact shoe for conveying current to a motor on board thereof; together with means adapted to automatically lower the current potential at the switch-terminals and at the junction of the third-rail sections or conductors each time the trolley or contact shoe passes from one sectional third rail or conductor to another, substantially as described.

18. In a sectional third-rail system of electric railways means for preventing abnormal arcing at the ends of adjacent third rails and at the switching-terminals in the switch-beams, consisting of a variable resistance carried by a car; in combination with means located in or adjacent to the road-bed for automatically causing said variable resistance to be gradually inserted in circuit with the motor on board the car until a minimum flow results at the time that the junction of the third rails is passed, and to correspondingly increase the current flow from the next adjacent third rail to the motor until a maximum flow is obtained, substantially as described.

19. In a safety system of electric railways a current feeder or main; a drawbridge carrying a sectional conductor constituting a part of the service-conductor for supplying current to the motor on board a car as it passes over the same, when in closed position; in combination with locking mechanism and circuits operatively connected therewith and so arranged that after a car approaches within a definite distance of either end of the bridge, the latter is locked so that it cannot be moved from its normal position, substantially as described.

20. A sectional third-rail safety system of electric railways provided with switching mechanism for effecting electrical connection of the third rails to and disconnection thereof from the current feeder or main; in combination with means for covering said third rails adjacent to the road-bed; together with a protecting-conduit for said rails consisting of side timbers located on opposite sides thereof and provided with means for effectually covering and protecting the current feeder or main and other conductors, substantially as described.

21. A safety system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors, a protecting-conduit consisting of side timbers located on opposite sides of said third rails or conductors and having channels or grooves for concealing the conductors of the system; in combination with switch-beams including switching devices for connecting the sectional conductors to and disconnecting them from the current feeder or main; together with a series of insulators supporting all of said parts, substantially as described.

22. In an electric-railway system a current feeder or main; sectional third rail or conductors normally disconnected therefrom; switching mechanism for connecting said sectional conductors to the current-feeder, and releasing-electromagnets for disconnecting them therefrom; said releasing-electromagnets being included in circuits connected each at one end directly to earth or return and extending in opposite directions to the near ends of adjacent sectional conductors, substantially as described.

700,129. ELECTRIC RAILWAY. CHARLES J. KETNER, New York, N. Y. Original application filed May 6, 1901, Serial No. 54,955. Divided and this application filed Sept. 25, 1901. Serial No. 76,664. (No model.)

Claim.—1. A safety system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and interlocking switching mechanism for positively connecting said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with safety-circuits, two for each sectional third rail or conductor, said safety-circuits including devices for releasing the interlocking conducting-terminals of the switches and signaling devices, and so connected to the power-house generator as to be normally without electrical current potential, substantially as described.

2. A safety system of electric railways embracing a current feeder or main and a series of sectional third rails or conductors normally disconnected therefrom; in combination with interlocking switching mechanism for positively connecting said sectional third rails or conductors to the current feeder or main and disconnecting them therefrom; together with a series of danger-signals, one for each sectional third rail or conductor, said danger-signals being connected permanently in circuit with said sectional third rails or conductors, and all of the conductors of the system, except the current feeder or main, being normally without current potential, substantially as described.

3. A safety system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and switching mechanism having conducting-terminals for connecting said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with releasing-electromagnets for the conducting-terminals of the switches, the individual coils of said releasing-magnets being included in circuit with safety-circuits normally without current potential and running in opposite directions and connected to earth and to the adjacent ends of adjoining sectional third rails or conductors; together with signaling mechanism included also in the safety-circuits, substantially as described.

4. A safety system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and switching mechanism for connecting said sectional conductors to and disconnecting them from the current feeder or main as a car or vehicle passes by or over the same; in combination with a series of safety-circuits, two for each sectional third rail or conductor, said safety-circuits being connected directly to the opposite ends of each of said conductors and extending to the opposite ends of the sectional third rails or conductors immediately in the front and rear thereof; together with signaling devices included in said safety-circuits, substantially as described.

5. A system of electric railways embracing a current feeder or main; a series of sectional third rails or conductors normally disconnected therefrom and a series of electromagnets switching devices for positively connecting and locking said sectional conductors to the current feeder or main as a car passes by or over the same; in combination with additional conductors normally without current potential and including electromagnets for releasing the conducting-terminals of the switches; together with signaling devices included in circuit with said releasing devices for indicating the electrical condition of the sectional third rails or conductors, there being one such signaling device for each sectional third rail or conductor, substantially as described.

6. A system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom, and a series of electromagnets switching devices for connecting said

sectional conductors to the current feeder or main as a car passes by or over the same; in combination with additional conductors, two connected to each sectional third rail or conductor, said additional conductors including electromagnets for releasing the conducting-terminals of the switches and signaling devices; said additional conductors being normally without current potential, substantially as described.

7. A system of electric railways embracing a current feeder or main and a series of sectional third rails or conductors normally disconnected therefrom; in combination with electromagnets switching devices for connecting said sectional third rails or conductors to the current feeder or main; together with electromagnets releasing devices for disconnecting them therefrom and a series of danger-signals connected permanently in circuit with the sectional third rails or conductors, the circuits including the danger-signals being normally without current potential, substantially as described.

8. An electric-railway system embracing a current feeder or main; a series of sectional third rails or conductors for a main track normally disconnected from the current feeder or main, and a siding having a third rail or conductor electrically connected with one of said third rails or conductors; in combination with switching devices for connecting the sectional conductors to and disconnecting them from the current feeder or main; together with signaling devices, and circuit connections between the siding third rail and the abovementioned switching devices, substantially as described.

9. A safety system of electric railways embracing a current feeder or main; a series of sectional third rails or conductors normally disconnected therefrom and switching mechanism for connecting said sectional conductors to the current feeder or main and disconnecting them therefrom as a car or vehicle passes by or over the same; in combination with a drawbridge carrying a sectional third rail or conductor and circuits and circuit connections between the main and side of the sectional third rails or conductors; together with signaling mechanism operatively included in circuit with the sectional conductor adjacent to the bridge and with the current feeder or main, substantially as described.

10. An electric railway including a draw or turn bridge therefor; in combination with circuits and circuit connections so arranged that when a car approaches either end of said bridge within a definite distance the latter is locked or held so that it cannot be disengaged until after the car has crossed the bridge; together with one or more signals for giving continuous indication of the fact that a car is near or upon the bridge, substantially as described.

11. An electric railway of the sectional third-rail type embracing a current feeder or main; a series of sectional third rails or conductors; switching devices for connecting the sectional conductors to the current feeder or main and signaling devices for indicating the electrical condition of the sectional third rails or conductors; together with branch circuits and switches adapted to connect the signaling devices directly with the current feeder or main, or to maintain the same in temporary connection therewith, substantially as described.

12. An electric railway embracing a current feeder or main; a series of sectional third rails or conductors normally disconnected therefrom; a series of electromagnets operatively connected with electromotive devices for controlling their movement; in combination with branch circuits and switches adapted to connect the electromotive devices directly with the current feeder or main, substantially as described.

13. A system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom, and a series of switching devices for connecting said sectional conductors to the current feeder or main as a car passes by or over the same; in combination with additional conductors, two for each sectional third rail or conductor, said additional conductors including electromagnets for releasing the conducting-terminals of the switches and electromotive devices operatively connected with electromagnets, substantially as described.

14. An electric railway embracing a current feeder or main; a series of sectional third rails or conductors normally disconnected therefrom; a series of switching devices for connecting said sectional conductors to and disconnecting them from the current feeder or main; a series of releasing-circuits operatively connected with the switching devices and permanently in circuit with the sectional conductors; in combination with a series of electromagnets operatively connected with electromotive devices included in the latter-mentioned releasing-circuits, said electromagnets being adapted to move in opposite directions, substantially as described.

700,130. ELECTRIC RAILWAY. CHARLES J. KETNER, New York, N. Y. Filed Dec. 5, 1901. Serial No. 54,724. (No model.)

Claim.—1. A safety system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and mechanically-actuated switching mechanism

for connecting said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with safety-circuits including devices for releasing the conducting-terminals of the switches, said safety-circuits being so connected to the power-house generator as to be normally without electrical current potential, and the entire arrangement being such that when a car is passing by or over a given sectional third rail or conductor the switch at the distant end of the sectional third rail or conductor immediately in the rear thereof is rendered temporarily inoperative until the car passes out of said section, substantially as described.

2. A safety system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and mechanically-actuated switching mechanism for connecting said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with safety-circuits, two for each sectional third rail or conductor, said safety-circuits including devices for releasing the conducting-terminals of the switches and so connected to the power-house generator as to be normally without electrical current potential, the entire arrangement being such that when a car is passing by or over a given sectional third rail or conductor the switches at the distant ends of the two adjacent sectional third rails or conductors are both rendered temporarily inoperative until the car passes out of the section over which it is traveling, substantially as described.

3. A safety system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and mechanically-actuated switching mechanism for connecting said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with safety-circuits including devices for releasing the conducting-terminals of the switches and signaling devices; said safety-circuits being so connected to the power-house generator as to be normally without electrical current potential, the entire arrangement being such that when a car is passing by or over a given sectional third rail or conductor the switch at the distant end of the sectional third rail or conductor immediately in the rear is rendered temporarily inoperative and a danger-signal is displayed, until the car passes out of said section, substantially as described.

4. A safety system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and mechanically-actuated switching mechanism for connecting said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with safety-circuits, two for each sectional third rail or conductor, said safety-circuits including devices for releasing the conducting-terminals of the switches and signaling devices, and so connected to the power-house generator as to be

normally without electrical current potential, the entire arrangement being such that when a car is passing by or over a given sectional third rail or conductor the switches at the distant ends of the sectional third rail or conductor immediately in the front and in the rear are rendered temporarily inoperative and danger-signals are displayed until the car passes out of said section, substantially as described.

5. A safety system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and mechanically-actuated switching mechanism for connecting said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with safety-circuits including devices for releasing the conducting-terminals of the switches, said safety-circuits being so connected to the power-house generator as to be normally without electrical current potential; together with additional means included in branches of the safety-circuits for enabling a motorman to cause his car or vehicle to enter upon a section adjacent to a preceding section over which a car is then passing, substantially as described.

6. A safety system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and switching mechanism for connecting said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with safety-circuits including devices for releasing the conducting-terminals of the switches and safety-circuits being so connected to the power-house generator as to be normally without electrical current potential; together with additional means for enabling a motorman to cause his car or vehicle to enter upon a section where a danger-signal is displayed, and additional signaling mechanism for giving a special indication or signal to the motorman of following cars that two or more cars are passing over adjacent preceding sections, substantially as described.

7. A safety system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and switching mechanism for connecting said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with safety-circuits including devices for releasing the conducting-terminals of the switches, said safety-circuits being so connected to the power-house generator as to be normally without electrical current potential; together with a series of permanent glowing or burning illuminating lamps or signals located one between each succeeding pair of third-rail sections, the entire arrangement being such that when a car is passing by or over a given sectional third rail or conductor the switch at the distant end of the sectional third rail or conductor immediately in the rear thereof is rendered temporarily inoperative until the car passes out of said section, and the motorman given a positive indication at all times of the beginning and ending of the third rails or conductors of the system, substantially as described.

8. A safety system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and switching mechanism for connecting said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with safety-circuits including devices for releasing the conducting-terminals of the switches and signaling devices; said safety-circuits being so connected to the power-house generator as to be normally without electrical current potential; together with a series of permanent glowing or burning illuminating lamps or signals located one between each succeeding pair of third-rail sections, the entire arrangement being such that when a car is passing by or over a given sectional third rail or conductor the switch at the distant end of the sectional third rail or conductor immediately in the rear thereof is rendered temporarily inoperative until the car passes out of said section, danger-signals displayed, and the motorman given a positive indication at all times of the beginning and ending of the third rails or conductors of the system, substantially as described.

9. A safety system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and switching mechanism for connecting said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with safety-circuits including devices for releasing the conducting-terminals of the switches, said safety-circuits being so connected to the power-house generator as to be normally without electrical current potential; together with manual circuit-breaking switches, one in each safety-circuit, the entire arrangement being such that when a car is passing by or over a given sectional third rail or conductor the switch at the distant end of the sectional third rail or conductor immediately in the rear thereof is rendered temporarily inoperative; or, any or all of the safety-circuits may be permanently interrupted in such manner that when the sectional third rails or conductors are connected to the current feeder or main they will remain thus connected, substantially as described.

10. A safety system of electric railways embracing a current feeder

or main and a series of sectional third rails or conductors normally disconnected therefrom; in combination with mechanically-actuated switching mechanism for connecting said sectional third rails or conductors to the current feeder or main and disconnecting them therefrom; together with a series of danger-signals connected permanently in circuit with the sectional third rails or conductors, the arrangement being such that the circuits including the danger-signals are normally without electrical current potential and that if a sectional third rail or conductor be left connected with the current feeder or main after a car has passed from over the same said signals will be continuously displayed, substantially as described.

11. A safety system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and mechanically-actuated switching mechanism having conducting-terminals for connecting said sectional conductors to the current feeder or main as a car or vehicle passes by or over the same; in combination with releasing-electromagnets for the conducting-terminals of the switches, the individual coils of said releasing-magnets being included in circuit with safety-circuits running in opposite directions and connected to earth and to the adjacent ends of distant sectional third rails or conductors, substantially as described.

12. A safety system of electric railways embracing a current feeder or main, a series of sectional third rails or conductors normally disconnected therefrom and mechanically-actuated switching mechanism for connecting said sectional conductors to and disconnecting them from the current feeder or main as a car or vehicle passes by or over the same; in combination with a series of safety-circuits, two for each sectional third rail or conductor, said circuits being connected directly to the opposite ends of said conductors and extending to the opposite ends of the sectional third rails or conductors in the front and rear thereof; together with signaling devices included in said safety-circuits, the arrangement being such that normally there is no electrical current potential in the signaling-circuits and that should any sectional third rail or conductor be left permanently connected with the current feeder or main, said signaling devices will be continuously displayed, substantially as described.

13. In an electric-railway system a current feeder or main, sectional third rails or conductors normally disconnected therefrom; mechanically-actuated switching mechanism for connecting said sectional conductors to the current-feeder and releasing-electromagnets for disconnecting them therefrom; said releasing-electromagnets being included in circuits connected at one end directly to the sectional conductors and extending in opposite directions to the distant ends of adjacent sectional conductors where they are connected to the return-circuit of the power-house generator, substantially as described.

700,181. LOCK-SWITCH MECHANISM FOR SEWING-MACHINE. JOHN G. BLACKWELL, Wynyard, Tasmania, Australia, assignor of one-half to John Bruce Irvine, Caulfield, Victoria, Australia, and Frederick Baker, Middle Brighton, Victoria, Australia. Filed Mar. 28, 1902. Serial No. 48,594. (No model.)

Claim.—In a lock switch forming mechanism for sewing-machines, the combination with a needle-thread-opening mechanism, a shuttle

adapted to be reciprocated past the needle of the machine, a pair of guide-rolls for said shuttle, a driver provided with a flat and a spring-pressed arm engaging with the shuttle for reciprocating it, a rod adapted to have one end thereof catch the loop of the needle-thread and draw the same across the shuttle-path and hold said thread during the passage of the shuttle so as to form a lock-stitch, a stud carried by the said arm, a traveler provided with a cam-groove in which engages said stud for operating the same, connections between the traveler and the driving means for the shuttle, means connected to the traveler for operating the same and said driving means simultaneously, and means connected to the under side of the traveler for clamping the same during its operation.

700,183. MACHINE FOR SETTING DIMENSIONS IN METAL. JOHN REIDEN, Rumburg-Sandau, Germany. Filed Feb. 14, 1902. Serial No. 54,118. (No model.)

Claim.—1. In a machine for setting hard substances in metal, the combination of a support for the metal piece, a lever having means for pressing the said substance into the metal, a tube connected with the lever, a port leading through the lever for directing a cooling liquid to the metal piece and a valve carried by the lever and controlling said port, substantially as described.

2. In combination, a yielding support for a metal piece, clamping bands or links having pivoted outer ends, said links being inclined toward each other and having their inner ends resting upon the yielding support with a space between for the metal piece, and means for pressing the same downwardly into the metal piece, said support yielding to permit the links to move downwardly to compress the metal piece between their adjacent ends and upon the same, substantially as described.

700,188. GUARD-BOARD FOR COACH-BOLTS. JAMES A. GUNN, Hiram, Ohio, assignor of one-half to George F. Hunt, Hiram, Ohio. Filed Feb. 12, 1902. Serial No. 52,261. (No model.)

Claim.—1. In a guard-board for a coach-roll, the combination, substantially as set forth, of a board supported over the coach-roll, front and rear clamp-strips secured to the lower edge thereof, layers of felt clamped between said clamp-strips and extending from the lower edge of said board to the jacket of the coach-roll and pressing their lower edges to the latter, and means for vertically adjusting said board.

2. In a guard-board for a coach-roll, the combination, substantially as set forth, of a board supported over the coach-roll and having a hark extending up into its lower edge and along its length and near one of its corners, clamp-strips secured to the front and rear faces of said board and projecting below the lower edge of the board, flexible material disposed between said clamp-strips and extending from the lower edge of said board down to the jacket of the coach-roll, clamp-strips engaging said board and clamp-strips and crossing said hark, and means for vertically adjusting said board.

3. In a guard-board for a coach-roll, the combination, substantially as set forth, of a supporting-board disposed over the coach-roll, a guard-board disposed against the front surface of said supporting-board and provided with an active edge engaging the jacket of the coach-roll, hangers lying against the front face of said guard-board and extending upwardly and then rearwardly over the upper edge of the guard-board, screws passing through the lower portions of said hangers and through vertical slots in said guard-board and into the supporting-board, and screws threaded downwardly through the upper portions of said hangers and engaging the upper edge of said guard-board.

4. In a guard-board for a coach-roll, the combination, substantially as set forth, of a supporting-board disposed over the coach-roll, a guard-board disposed against the front surface of said supporting-board and provided with an active edge engaging the jacket of the coach-roll, hangers lying against the front face of said guard-board and extending upwardly and then rearwardly over the upper edge of the guard-board and secured to said supporting-board, screws passing through the lower portions of said hangers and through vertical slots in said guard-board and into the supporting-board, and screws threaded downwardly through the upper portions of said hangers and engaging the upper edge of said guard-board.

700,184. TROLLEY. MINNAN P. CHAMBERLAIN, Pittsburgh, Pa. Filed Oct. 25, 1901. Serial No. 73,973. (No model.)

Claim.—1. In combination with a trolley-pole, a bracket-arm connected to the upper end thereof, a hark journaled in said bracket-arm, and a forked spring connected to the trolley-pole and to the axle of the trolley-wheel, substantially as shown and described.

2. In a trolley, the combination with the trolley-pole, of a tubular bracket-arm connected to the upper end of the pole, a hark journaled in said bracket-arm, a trolley-wheel mounted in said hark, and a forked spring connected to the trolley-pole with slotted ends engaging the axle of the trolley-wheel; as and for the purpose described.

3. In a trolley, the combination with the tubular trolley-pole, of a tubular bracket-arm connected to the upper end of the pole and having a barrel or sleeve on its free end, a trolley-harp having a tubular journal-shaft fitted in said sleeve or barrel, a trolley-wheel mounted in said harp, and a forked spring connected to the trolley-pole and having forked ends engaging the axle of the trolley-wheel.

4. In combination with a trolley-pole, a bracket-arm connected to the upper end thereof, a hark journaled in said bracket-arm and carrying a wheel having its axle in line with the trolley-pole when the wheel is in full contact with the wire, and a spring connected to the trolley-pole and having a slotted end to receive the axle of the trolley-wheel, substantially as described.

5. In a trolley, the combination with the trolley-pole, of a tubular segment-shaped bracket-arm connected to the upper end of the trolley-pole, a trolley-harp journaled for vertical and relative movement in said bracket-arm, a wheel mounted in said harp and adapted when in engagement with the wire to have its axle in line with the trolley-pole, and a spring connected to the trolley pole and engaging the axle of the trolley-wheel, as and for the purpose described.

6. In a trolley, the combination with a trolley-pole, and a tubular fitting mounted on the upper end of said pole, of a tubular segment-shaped bracket-arm having its one end braced into the fitting carried by the trolley-pole, a barrel or sleeve carried by said bracket-arm at its outer end, a tubular journal-shaft fitted in the sleeve vertically in said barrel or sleeve, a hark carried by the said journal-shaft, a trolley-wheel mounted in said harp and adapted to lie with its axle in central longitudinal alignment with the trolley-pole when the wheel is depressed by contact with the

current-wire, and a spring exerting its pressure at all times against the wheel in hold the latter in contact with the current-wire, substantially as described.

7. In a trolley, the combination with a trolley-pole, of a bracket-arm connected to the upper end thereof, a bar journaled for vertical movement in said bracket-arm, a trolley-wheel mounted in said bar and adapted when in full contact with the trolley-wire to have its axle in line with the trolley-pole, and a spring connected to one end of the trolley-pole and its other end engaging the axle of the trolley-wheel, as and for the purpose described.

700,185. APPARATUS FOR ROASTING AND COOLING ORBS.
WILLIAM G. DAVIS, Denver, Colo. Filed Jan. 6, 1902. Serial No. 93,601.
(No Model.)

Claim.—1. In a roasting apparatus, the combination with a roasting chamber and hearth, of a rabble-carriage located in the roasting-chamber and comprising hollow side bars forming water-receptacles, open to permit evaporation in the roasting-chamber, a transverse bar provided with rabble plevs or blades, the side bars occupying positions on opposite sides of the hearth, and means for propelling the rabble-carriage.

2. In an apparatus of the class described, the combination with a roasting chamber and hearth, of hollow side bars forming water-receptacles located on opposite sides of the hearth, a transverse bar connecting the side bars, and a sleeve movably mounted on the transverse bar, and provided with rabble plevs or blades, and means for propelling the rabble-carriage.

3. The combination with a combustion chamber and hearth, of hollow side bars forming water-receptacles located on opposite sides of the hearth, a hollow transverse bar connecting the side bars, and having open ends to allow the water to enter from the side bars, and a rabble-sleeve mounted to rotate on the transverse bar.

4. The combination with a combustion chamber and hearth, of a rabble-carrier located in the said chamber and composed of hollow side bars forming water-receptacles, hollow transverse bars connecting the side bars and open to allow the water to enter from the side bars, and rabble plevs or blades mounted on one of the transverse bars, the side bars being located on opposite sides of the hearth, and suitable means for propelling the rabble-carriage.

5. The combination with a chamber and hearth, and a source of heat connected with the chamber, of a rabble-carriage composed of hollow side bars forming water-receptacles open at the top to permit free evaporation, a hollow transverse bar connecting the side bars and open to allow the water to enter from the side bars, rabble plevs or blades mounted on the transverse bar, and suitable means for propelling the rabble-carriage.

6. The combination with a chamber, a hearth, and a source of heat, of a rabble-carriage located in the chamber and composed of hollow side bars forming water-receptacles located on opposite sides of the hearth, and open at the top, the lower edges of the side bars being provided with coggled racks, transverse bars connecting the side bars and open to allow the water to enter from the side bars, rabble plevs or blades mounted on one of the transverse bars, and propelling-means suitably journaled along the sides of the hearth and provided with cogs engaging the racks of the side bars for actuating the rabble-carriage.

7. The combination with a hearth, of side bars located on opposite sides of the hearth, their lower edges being partly coggled and partly plain, transverse bars connecting the side bars, rabble plevs or blades mounted on one of the transverse bars, and wheels located along the sides of the hearth for supporting and propelling the rabble-carriage, the c-ld wheels having a coggled rim to engage the cogs of the side-bar racks, and a plain rim to engage the plain portions of the rack-bars, forming the support for the carriage, whereby the coggled portions of the wheels are relieved of the weight and only required to perform the propelling function, substantially as described.

8. In an apparatus of the class described, the combination with a hearth upon which ore may be spread for roasting or cooling purposes, of side bars arranged to travel on opposite sides of the hearth, transverse bars connecting the side bars, wheels located along the hearth sides and engaging the side bars in operative relation for propelling purposes, a rabble-sleeve movably mounted on one of the transverse bars, said sleeve being provided with plevs or blades, a toothed wheel fast on the rabble-sleeve, a pawl or dog pivotally mounted on one of the side bars and engaging the toothed wheel to prevent rotation in one direction, and a trip located at each extremity of the hearth for engaging the toothed wheel of the rabble-sleeve and imparting a partial rotation thereto, substantially as described and for the purpose set forth.

9. The combination with a hearth, of side bars arranged to travel along the hearth on opposite sides, connecting-bars extending transversely across the hearth, a sleeve movably mounted on one of the transverse bars, a toothed wheel fast on each extremity of the sleeve, a dog or pawl pivoted on each side bar and engaging the adjacent toothed wheel to prevent the rotation of the latter in one direction, and a tripping device suitably located to engage and rotate the toothed wheel, whereby a partial rotation is imparted to the rabble-sleeve at predetermined intervals, substantially as described and for the purpose set forth.

10. The combination with a hearth, of carriage side bars located and arranged to travel on opposite sides of the hearth, bars extending transversely across the hearth and connecting the side bars, a sleeve movably mounted on one of the transverse bars and composed of interlocking sections, rabble plevs or blades mounted on the sleeve, and means for imparting a partial rotation to the sleeve at predetermined intervals, substantially as described.

11. The combination with a hearth, of carriage side bars arranged to move on opposite sides of the hearth, a transverse bar connecting said side bars, a sectional sleeve mounted to rotate on said bar, each sleeve-section being provided with two rabble blades or plevs diametrically located, and means for imparting a partial rotation to the rabble-sleeve in the opposite direction at predetermined intervals, substantially as described.

12. The combination with a hearth, of side bars located and adapted to travel on opposite sides of the hearth, a bar extending transversely across the hearth and connecting the side bars, a sleeve mounted to rotate on said bar, rabble plevs or blades diametrically located on opposite sides of the sleeve, the oppositely-located blades being parallel and adjacently connected with the sleeve, substantially as described.

13. The combination with a hearth, of carriage side bars arranged and adapted to travel on opposite sides of the hearth, a transverse bar connecting the side bars, a sleeve mounted to rotate on said bar, rabble plevs or blades diametrically located on opposite sides of the sleeve, the opposite blades being parallel, a toothed wheel fast on each extremity of the sleeve, a dog mounted on each side bar and engaging the adjacent toothed wheel to prevent the movement of the sleeve in one direction, and a depending tripping device arranged to engage each toothed wheel and impart a partial rotation to the rabble-sleeve in the opposite direction, the tripping device being pivoted to swing freely from the vertical position in one direction, but locked against movement in the opposite direction, substantially as shown and described.

14. The combination with a hearth, of side bars located and arranged to travel on opposite sides of the hearth, transverse bars connecting the side bars, rabble plevs mounted on one of the transverse bars, the side bars having coggled racks on their lower edges, coggled propelling-wheels located along the sides of the hearth at suitable intervals, and engaging the side-bar racks, shafts extending longitudinally along the sides of the hearth and geared to the carriage-propelling wheels, means for operating the shafts and means connected with the operating mechanism and acted on

by the rabble-carriage at each end of the hearth, for automatically reversing the movement of the longitudinal shafts and carriage-propelling wheels, whereby the carriage is made to move back and forth over the hearth, substantially as shown and described.

15. In an apparatus of the class described, the combination of a combustion-chamber and a hearth, with a rabble-carriage provided with side bars arranged to travel on opposite sides of the hearth, transverse bars connecting the side bars, rabble plevs mounted on one of the transverse bars, propelling-wheels located at suitable intervals along the hearth sides and engaging the carriage side bars in operative relation, shafts located outside of the chamber and geared to the propelling-wheels for operating the carriage, means for operating the shafts and means connected with the shaft-operating mechanism, located at each end and outside of the chamber, for reversing the movement of the operating-shafts, said means being actuated by a carriage side bar, the end walls of the chamber being being open to allow the side-bar to protrude for the purpose set forth.

16. The combination with a chamber and a hearth, of side bars located and arranged to travel on opposite sides of the hearth, a transverse bar connecting the side bars and provided with rabble blades or plevs, means located outside of the chamber for operating the carriage and causing it to move longitudinally over the hearth, and means exteriorly located at each extremity of the chamber for reversing the movement of the carriage-operating mechanism, the said reversing means being actuated by the rabble-blades, the end walls of the chamber being provided with openings to allow the carriage side bars to protrude for the purpose set forth.

17. In an apparatus of the class described, the combination with a combustion-chamber and a hearth, of a rabble-carrier located in said chamber and having a part arranged to protrude at each end of the chamber whose ends and walls are provided with openings for the purpose, means for causing the carriage to travel longitudinally, and means located at each end of the chamber and acted on by the protruding part of the rabble-carriage, whereby the carriage-operating mechanism is automatically reversed, and the carriage made to travel back and forth in the chamber, substantially as described.

18. In an apparatus of the class described, the combination with a roasting chamber and hearth, of a rabble-carriage provided with side bars located and arranged to travel on opposite sides of the hearth, propelling-wheels engaged by the carriage side bars in operative relation, two longitudinal shafts located outside the chamber and connected to operate the rabble-carriage-propelling wheels, the two longitudinal shafts being connected to operate in unison, fast and loose pulleys connected with one of the longitudinal shafts, belts for the pulleys, belt-shifting devices for reversing the rotation of the shaft, the rabble-carriage being provided with a part protruding through openings formed in the end walls of the chamber, and means located at each end of the chamber and connected with the belt-shifting devices, for operating the latter, the said means being automatically actuated by the carriage-protruding part, substantially as described.

19. In an apparatus of the class described, the combination with a chamber and hearth, of a rabble-carriage located in said chamber which is provided with openings in its end walls, the carriage being provided with parts adapted to protrude through said openings, a shaft located outside the chamber and connected to cause the rabble-carriage to move longitudinally therein, means for operating said shaft, and means located exteriorly at each end of the chamber and arranged to be actuated by the carriage-protruding parts, for reversing the shaft-operating mechanism, substantially as described.

20. In an apparatus of the class described, the combination with a chamber and hearth, of a rabble-carriage arranged to move longitudinally in said chamber which is provided with openings in its end walls, the carriage being provided with parts adapted to protrude through said openings, a shaft located outside the chamber, means connected with and operated by said shaft for actuating the carriage in the chamber, fast and loose pulleys mounted on said shaft, belts connected with said pulleys, belt-shifting devices, and means located at each end of the chamber and connected with said devices for shifting the belts and reversing the rotation of the shaft, said means being actuated by the protruding part of the carriage, whereby the latter is caused to travel back and forth in said chamber, substantially as described.

21. In an apparatus of the class described, the combination with a chamber and hearth, of a rabble-carriage arranged to move longitudinally in said chamber which is provided with openings in its end walls, the carriage being provided with parts adapted to protrude through said openings, a shaft located outside of the chamber, means connected with and operated by said shaft for actuating the carriage in the chamber, fast and loose pulleys mounted on said shaft, belts connected with said pulleys, belt-shifting devices, a rock-shaft on which said devices are mounted, an arm also fast on the rock-shaft, another rock-shaft provided with a crank-arm, a link connecting the two arms, a third arm mounted on one of the

rock-shafts, and lying in the path of the carriage-protruding part at the end of the chamber, whereby the belt-shifting devices are actuated and the movement of the carriage-operating shaft reversed, substantially as described.

22. In an apparatus of the class described, the combination with a chamber and hearth, of a rabble-carriage located and arranged to move longitudinally in said chamber which is provided with openings in its end walls, the carriage having parts adapted to protrude through said openings, a shaft located outside of the chamber, means connected with and operated by said shaft for actuating the carriage in the chamber, pulleys mounted on said shaft, belts connected with said pulleys, belt-shifting devices, a rock-shaft on which said devices are mounted and made fast, an arm also fast on the rock-shaft, another rock-shaft provided with a crank-arm, a link connecting the two arms, a third arm mounted on one of the rock-shafts and lying in the path of the carriage-protruding part at one end of the chamber, a rock-shaft located at the opposite end of the chamber, a crank-arm fast on the last-named rock-shaft, and located in the path of the carriage-protruding part, a rocking bar fast on the rock-shaft at each extremity of the chamber, each bar projecting on equal distance from the rock-shaft in opposite directions, and rods or cables connecting the corresponding extremities of the two rocking bars, whereby as soon as the rabble-carriage reaches its limit of movement in either direction, its operating mechanism is reversed and it is caused to travel in the opposite direction.

23. The combination with a roasting or drying chamber, and a suitable hearth, of a rabble-carriage movable longitudinally in the chamber and provided with hollow side bars forming water-receptacles, a hollow transverse rabble-bar connecting the side bars and open to allow the water from the side bars to enter, and a valve-controlled water-supply conduit located exteriorly at one end of the roasting-chamber, for supplying the carriage with water, the valve of the conduit being automatically opened by the movement of the carriage.

24. The combination with a roasting or drying chamber and a hearth, of a rabble-carriage located in said chamber and adapted to hold water, means for operating the carriage, whereby it is made to travel back and forth in said chamber which is provided with openings in its end walls, the carriage having a part adapted to protrude through said openings, a valve-controlled water-supply conduit located outside the chamber, and means for opening the valve, said means being actuated by the protruding part of the carriage, which protruding part is connected to receive the water and conduct it to the other carriage parts.

25. The combination with a roasting chamber and hearth, of a rabble-carriage adapted to move back and forth in said chamber and provided with hollow side bars forming water-receptacles, the end wall of the chamber being open to allow the side bars to protrude, a hollow rabble-bar connecting the side bars and open to allow the water from the side bars to enter, a water-supply conduit exteriorly located at one end of the chamber, a valve for controlling the discharge of water from said conduit, operating means connected with the valve, said means being actuated by a protruding side bar of the carriage, whereby the valve is automatically opened and closed at predetermined intervals, the said bar being in position to receive the necessary water for supplying the carriage.

26. In an apparatus of the class described, the combination with a roasting chamber and hearth, of a rabble-carriage located therein and adapted to move back and forth, said carriage having side bars forming water-receptacles open at the top, and a hollow transverse bar connecting the side bars and communicating therewith to permit circulation of water, rabble blades or plevs mounted on the transverse bar, one end wall of the roasting-chamber having openings to allow the hollow side bars to protrude, a water-supply conduit exteriorly located, a valve for controlling the discharge from said conduit, and means connected with the valve and lying in the path of the free extremities of the side bars, whereby the said valve is opened, substantially as described.

27. In an apparatus of the class described, the combination with a roasting chamber and hearth, of a rabble-carriage constructed to hold water and provided with a part adapted to protrude from the end of the chamber the latter being provided with an opening for the purpose, an exteriorly-located water-supply device, a valve connected with said device and arranged to be opened by the protruding part of the rabble-carriage when traveling in one direction, and closed by said part when traveling in the opposite direction, substantially as described.

28. The combination with a chamber and hearth, of a rabble-carriage adapted to hold water and being arranged to protrude from the end of the chamber whose wall is provided with an opening for the purpose, a water-supply conduit exteriorly located and provided with a valve, a lever connected with the valve and lying in the path of the protruding part of the carriage, whereby the lever is actuated to open the valve when the carriage is moving in one direction, and to close the valve when the carriage is moving in the opposite direction, substantially as described and shown.

29. The combination with a resting chamber and hearth, of a rabbit-carriage constructed to hold water and provided with a part adapted to protrude from the resting-chamber and conduct water to the portion of the carriage within the chamber, the latter having an opening in its end wall to allow the said parts to protrude, water-supply means provided with a valve controlling the discharge-opening, a lever connected with said valve and provided with two arms, one of which lies in the path of the carriage-protruding part when it is moving in one direction, whereby the lever is actuated to open the valve and allow the water to flow therefrom into the protruding part of the carriage, the other lever-arm being thrown to a position to be engaged by the carriage during its movement in the opposite direction, whereby the valve is closed.

30. The combination with a resting chamber and hearth, of a rabbit-carriage located therein and adapted to move back and forth as described, the said carriage having a protruding part adapted to receive and conduct water to the other parts of the carriage, the said part being open to permit the escape of water by evaporation in the resting-chamber, the end wall of the chamber having an opening to allow the said part of the carriage to pass through, substantially as described.

31. The combination with a chamber and hearth, of a rabbit-carriage adapted to hold and retain water and permitting escape only by evaporation, said carriage having a protruding part adapted to receive and conduct water to the parts of the carriage within the chamber, and a water-supply means provided with a valve arranged to be opened and closed by the protruding part of the carriage as it moves in opposite directions, substantially as described.

32. The combination with a chamber and hearth, of a carriage arranged to move back and forth in said chamber and provided with a protruding part adapted to receive water and conduct it to the other parts of the carriage which is constructed to contain water, permitting escape only by evaporation, a water-supply source located outside the chamber, a valve controlling the discharge from said source, a triple-armed lever, one arm of which is connected with the valve, another arm lying in the path of the carriage-protruding part as it moves forwardly or out of the chamber, whereby the lever is actuated to open the valve, the third lever-arm being thrown by said action into the path of the protruding part as it moves in the opposite direction, whereby the lever is actuated to close the valve.

33. The combination with a resting chamber and hearth, of a rabbit-carriage located in the chamber and constructed to hold water and permit escape by evaporation, said carriage having a protruding part adapted to receive water from a source outside of the chamber, and conduct it to the portion of the carriage within the chamber, and means located outside the chamber and automatically controlled by the carriage-protruding part, whereby the carriage is supplied with water while the said carriage part is outside of the chamber, the water discharge being cut off when the said part moves into the chamber.

34. The combination with a resting chamber and hearth, of a rabbit-carriage arranged to move back and forth within the chamber, the said carriage being constructed to hold water and permit escape by evaporation, the said carriage having a protruding part adapted to receive and conduct water from a point outside the chamber to the portion of the carriage within the chamber, the wall of the chamber having an opening through which the said carriage part passes, a water-supply source located outside the chamber and provided with a valve, a crank-arm attached to the valve-stem, a triple-armed lever, one arm of which is connected with the valve-stem, another arm located in the path of the protruding part as it moves out of the chamber, whereby the lever is actuated to open the valve and allow the water to pass into the protruding part of the carriage, the third arm of the lever being thrown into the path of the carriage protruding part as it moves in the opposite direction or into the chamber, whereby the lever is actuated to close the valve.

35. The combination with a chamber and hearth, of a rabbit-carriage arranged to move back and forth within the chamber and over the hearth, the said carriage being adapted to hold water and permit its escape by evaporation, the carriage being also provided with a protruding part adapted to receive water and conduct it to the part of the carriage within the chamber, the wall of the chamber having an opening to allow the carriage protruding part to pass outside the chamber, a water-supply source located outside the chamber, a valve controlling the escape of water from said source, a crank connected with the valve, a lever, a link connecting the said crank with one arm of the lever which is provided with another arm lying in the path of the protruding part as it moves out of the chamber, whereby the valve is opened, the lever having a third arm which is engaged by the carriage protruding part as it moves in the opposite direction, whereby the valve is closed.

36. The combination with a resting chamber and hearth, and a cooling-hearth located above the resting-chamber, of a discharge-chute at one extremity of the chamber, means for advancing the ore in the rest-

ing-chamber and discharging the roasted ore from the chamber through said chute at predetermined intervals, a basket for receiving the ore discharged, means for elevating the basket and discharging its contents upon the cooling-hearth and returning the empty basket to the mouth of the discharge-chute, the movement of the basket-carrying mechanism being timed to harmonize with the operation of the ore-discharge means, whereby the basket is always in place at the time the ore is discharged, and means for advancing the ore upon the cooling-hearth, said means being independent of the ore-advancing and discharge means within the resting-chamber.

37. The combination with a resting chamber and hearth, and a cooling-hearth located above the resting-chamber, of a discharge-chute located at the rear extremity of the resting-chamber, means for advancing the ore and discharging it through said chute at predetermined intervals, an ore-receptacle adapted to receive the ore discharged from the chute, carrying-chains with which said ore-receptacle is connected, and means for actuating the chains whereby the ore-receptacle is elevated to the cooling-hearth, means for dumping the basket as it is moved along by the carrying-chains, means for reversing the movement of the carrying-chains, whereby the ore-receptacle is returned to the mouth of the ore-discharge chute, the movement of the carriage-chains being timed to harmonize with the operation of the ore-discharge mechanism, to bring said receptacle into place at the proper time to receive the ore discharged, and means for advancing the ore upon the cooling-hearth, said means being independent of the ore-advancing means within the resting-chamber.

38. The combination with a resting chamber and hearth, and a cooling-hearth located above the resting-chamber, of an ore-discharge chute located at the rear extremity of the resting-chamber, means located within the chamber for advancing the ore in the resting-chamber and discharging it through said chute at predetermined intervals, a basket located outside the chamber and constructed to receive the ore discharged from the chute, carrying mechanism attached to the basket for elevating the latter to a position above the cooling-hearth, means for dumping the contents of the basket upon the cooling-hearth while the carrying means is moving in one direction, means for reversing the movement of the carrying mechanism when the basket is dumped, whereby the basket is returned in the path of its original travel, to a position below the mouth of the discharge-chute, the operation of the basket-carrying and ore-discharge mechanism being timed to operate in unison, and means for advancing the ore upon the cooling-hearth, said means being independent of the ore-advancing means within the resting-chamber, substantially as described and for the purpose set forth.

39. The combination with an ore-resting chamber and hearth, and a cooling-hearth, of means for advancing the ore within the resting-chamber, discharging it from the said chamber at predetermined intervals, a receptacle adapted to receive the ore discharged from the resting-chamber, means whereby the ore-receptacle is carried to and discharged upon the cooling-hearth, and means to receive again the ore discharged from the resting-chamber, the ore-receptacle-carrying mechanism being timed to harmonize with the discharge mechanism, and means for advancing the ore upon the cooling-hearth, said means being independent of the ore-advancing means within the resting-chamber, substantially as described and for the purpose set forth.

40. The combination with a resting chamber and hearth, and a cooling-hearth located above the resting-chamber, of means located within the resting-chamber for advancing the ore in the resting-chamber and discharging it therefrom at predetermined intervals, a basket constructed to receive and hold the ore discharged, carrying means for the basket, whereby the latter is elevated to the cooling-hearth, means located in proximity to the hearth for dumping the contents of the basket upon the cooling-hearth as the basket is traveling in one direction, means for reversing the travel of the basket to receive the ore discharged from the chamber, the operation of the ore-discharge and the basket-carrying mechanism being timed to produce this result, and means for advancing the ore upon the cooling-hearth, said means being independent of the ore-advancing means within the resting-chamber.

41. The combination with a resting-chamber, a resting-hearth and a cooling-hearth located above the resting-hearth, of an ore-discharge chute located at the rear extremity of the resting-chamber, means located within the chamber for discharging the ore through said chute at predetermined intervals, a basket to receive the ore from the chute, endless carrying-chains connected with the basket, means for operating the chains to carry the basket to the cooling-hearth, means for discharging the basket contents during its forward travel, and means for reversing the travel of the carriage-chains to bring the basket again to the discharge-chute, the movement of the endless carrying-chains and the ore-discharge mechanism within the chamber being timed to harmonize, substantially as described.

42. The combination with a resting-chamber, a resting-hearth, chute located at the rear extremity of the said chamber, a basket con-

and a cooling-hearth located above the resting-chamber, of a discharge-chute to receive the discharge through the chute, endless carrying-chains connected with the basket, means for operating the chains whereby the basket is carried to the cooling-hearth, and a stepped device mounted in proximity to the cooling-hearth and lying in the path of the basket during its forward travel, whereby the basket is first tipped onto one side, and finally inverted to dump its contents upon the hearth, and means for returning the basket-carrying mechanism to the discharge-mouth of the chute to receive the next charge of ore, substantially as described.

43. The combination with a resting-chamber, a resting-hearth, and a cooling-hearth located above the resting-hearth, of a discharge-chute protruding from the rear extremity of the resting-chamber, and of a width equal to the width of the chamber, a basket having a length equal to the width of the discharge-chute, endless chains to which the ends of the basket are respectively attached, means for operating the chains to carry the basket upwardly to the cooling-hearth, means mounted in proximity to the cooling-hearth, for automatically dumping the basket and discharging the contents upon the cooling-hearth, and means for reversing the movement of the carrying-chains, whereby the basket is returned to its position below the mouth of the discharge-chute, suitable means located within the resting-chamber for discharging ore through the chute at predetermined intervals, the movement of the said means and that of the basket-carrying device being limited to cooperate for the purpose set forth.

44. The combination with a resting-chamber, a resting-hearth, and a cooling-hearth located above the resting-chamber, of a rabbit-carriage located in the resting-chamber, a discharge-chute at the rear extremity of the chamber, means for causing the carriage to travel back and forth in said chamber whereby ore is advanced and discharged through the chute at predetermined intervals, means for taking each discharge of ore from the resting-chamber and elevating it to the cooling-hearth, the operation of the ore-carrying means with reference to the movement of the rabbit-carriage being timed, substantially as described, and means for advancing the ore upon the cooling-hearth, said means being independent of the ore-advancing means within the resting-chamber.

45. The combination with a resting-chamber, a resting-hearth and a cooling-hearth located above the resting-chamber, of a rabbit-carriage located in the chamber, a discharge-chute at the rear extremity of the chamber, means for causing the carriage to travel back and forth in said chamber, whereby the ore is advanced and discharged through the chute at predetermined intervals, means for taking each discharge of ore from the resting-chamber and elevating it to the cooling-hearth, the operation of the ore-carrying means with reference to the movement of the rabbit-carriage being timed as described, and a rabbit-carriage mounted to move over the cooling-hearth and arranged to cause the ore to travel from the point of discharge at the rear extremity of the cooling-hearth, to the opposite extremity of the same, said cooling-hearth carriage being distinct and separate from the carriage within the resting-chamber, substantially as described.

46. In an ore resting and cooling apparatus, the combination with a resting chamber and hearth, of a rabbit-carriage located in the resting-chamber and arranged to cause the ore to travel toward the rear extremity thereof, the said carriage having side bars located on opposite sides of the hearth, propelling-rollers located along the sides of the hearth, engaging the side bars of the carriage, shafts located outside the resting-chamber and extending longitudinally thereof, said shafts being geared to the carriage-propelling rollers, the two longitudinal shafts being connected in operative relation, means for transmitting motion to one of said shafts, a cooling-hearth, a rabbit-carriage arranged to cause the ore to travel from its rear extremity toward the forward extremity thereof, propelling-rollers engaging said carriage, shafts connected with the said rollers for operating the same, and connected with each other in operative relation, means for transmitting motion from one of the operating-shafts of the resting-chamber carriage to one of the similar shafts of the cooling-hearth carriage, means for automatically reversing the rotation of the carriage-operating shafts when the carriages have reached their limit of movement in either direction, the rabbit-carriages of the resting-chamber being arranged to cause the ore to travel rearwardly and discharge at predetermined intervals at the rear extremity of the chamber, while the rabbit-carriage of the cooling-hearth is arranged to cause the ore to travel forwardly, and means for receiving each ore-discharge from the resting-chamber and automatically elevating it upwardly to the rear extremity of the cooling-hearth, the operation of the ore receiving and elevating means being so timed with reference to the travel of the rabbit-carriage, that the ore is carried upwardly and discharged on the cooling-hearth during the forward movement of the carriage, the ore receiving and elevating mechanism making the return movement while the carriage is traveling rearwardly, substantially as described.

47. The combination with a resting chamber and hearth, of a rabbit-carriage located in the resting-chamber and constructed to hold wa-

ter, means for operating the carriage, a source of water-supply located outside the chamber, a valve for controlling the discharge from said source, means connected with the valve and operated by the carriage for opening the valve to supply the carriage with water when the carriage is moving in one direction, means actuated by the carriage for reversing the carriage-operating mechanism simultaneously with the opening of said valve, whereby the carriage begins the reverse movement, and means actuated by the carriage for closing the valve as the carriage begins the return movement, substantially as described.

48. The combination with a resting chamber and hearth, of a carriage movable longitudinally in said chamber and arranged to hold water and permit escape thereof by evaporation, said carriage having a protruding part constructed to receive water and conduct it to the carriage within the chamber, a valve-controlled water-supply source located outside the chamber, a connection with the valve, acted on by the protruding part of the carriage for opening the valve when the carriage is moving in one direction, means for operating the carriage, and means also acted on by the protruding part of the carriage for reversing the movement of the operating mechanism simultaneously with the opening of said valve, and means acted on by the carriage protruding part for closing the valve as the carriage begins its return movement.

49. The combination with a resting chamber and hearth, of a rabbit-carriage movable longitudinally in said chamber and provided with hollow side bars forming water-receptacles, and hollow connecting-bars communicating with the water-receptacles of the side bars which are adapted to protrude from the resting-chamber, the latter having openings in its end walls to allow the said bars to protrude, means for opening the carriage, means actuated by the protruding side bar for reversing the carriage-operating mechanism when the carriage has reached its forward limit of movement, and means connected with the valve of the water-supply source and acted on by a carriage side bar for opening the valve, and means also acted on by a carriage side bar for closing the valve as the carriage begins its reverse movement.

50. The combination with a resting chamber and hearth, of a rabbit-carriage movable longitudinally in said chamber and provided with hollow side bars forming water-receptacles located on opposite sides of the hearth, hollow bars connecting the side bars and communicating with the water-receptacles therein, the end walls of the chamber being open to allow the side bars to protrude, means for operating the rabbit-carriage, means operated from either extremity of the chamber by a protruding side bar for automatically reversing the carriage-operating mechanism, whereby the carriage is caused to move back and forth in said chamber, a valve-controlled water-supply source located at one extremity of said chamber, and means acted on by the carriage side bar for opening said valve as the carriage reaches its limit of movement in one direction, and for closing said valve as the carriage moves in the opposite direction.

51. The combination of a resting-chamber, a resting-hearth within said chamber, means for stirring and advancing the ore upon the resting-hearth, and discharging it from the resting-chamber, a cooling-hearth, means for receiving the ore from the resting-chamber and discharging it upon the cooling-hearth, and means for stirring and advancing the ore upon the cooling-hearth, said means being independent of the ore stirring and advancing means within the resting-chamber.

52. The combination of a resting-chamber, a resting-hearth located therein, means for stirring and advancing the ore upon the resting-hearth and discharging the roasted ore from the said chamber, a cooling-hearth located above the resting-chamber, means for elevating the ore from the resting-chamber and discharging it upon the cooling-hearth, and means for stirring and advancing the ore upon the cooling-hearth, said means being independent of the ore stirring and advancing means within the resting-chamber.

700,186. REVERSIBLE GALVANIC BATTERY. THOMAS A. BROWN, Llewellyn Park, N. J., assignor to Edison Storage Battery Company, a Corporation of New Jersey. Filed Mar. 6, 1901. Renewed Mar. 2, 1908. Serial No. 98,098. (No Model.)

Claim.—1. An element for a reversible galvanic cell, consisting of electrolytically-reducible oxide of iron, substantially as set forth.

2. An element for a reversible galvanic cell, consisting of electrolytically-reducible oxide of iron in finely-divided form, substantially as set forth.

3. A reversible galvanic cell, comprising an alkaline electrolyte, an element consisting of oxide of iron, and a second element having a depolarizing material not soluble in such solution, substantially as set forth.

4. A reversible galvanic cell, comprising an alkaline electrolyte, an element consisting of oxide of iron in finely-divided form, and a second element having a depolarizing material not soluble in such solution, substantially as set forth.

5. An element for a reversible galvanic cell, consisting of oxide of iron and graphite mixed therewith, substantially as set forth.

6. An element for a reversible galvanic cell, consisting of scale oxid of iron and manganese, foliated or flake-graphite mixed therewith, substantially as set forth.

7. An element for a reversible galvanic cell, consisting of scale oxid of iron in flake-divided form and graphite mixed therewith, substantially as set forth.

8. A reversible galvanic cell, comprising an alkaline electrolyte, an element consisting of scale oxid of iron and graphite mixed therewith, and a second element having a depolarizing material not soluble in such solution, substantially as set forth.

9. A reversible galvanic cell, comprising an alkaline electrolyte, an element consisting of scale oxid of iron, and a second element having a depolarizing element consisting of an oxid of a magnetic metal other than iron, substantially as set forth.

10. A reversible galvanic cell, comprising an alkaline electrolyte, an element consisting of scale oxid of iron, and a second element having a depolarizing material consisting of oxid of nickel, substantially as set forth.

11. A reversible galvanic cell, comprising an alkaline electrolyte, an element consisting of flake-divided scale oxid of iron mixed with graphite, and a second element having a depolarizing element consisting of oxid of nickel mixed with flake-graphite, substantially as set forth.

700,187. REVERSIBLE GALVANIC BATTERY. THOMAS A. EDISON, Llewellyn Park, N. J., assignor to Edison Storage Battery Company, a Corporation of New Jersey. Filed Mar. 2, 1901. Serial No. 46,986. (No model.)

Claim.—1. A grid or plate for alkaline reversible galvanic batteries, the immersed surface of which is unaffected by the alkaline solution and having a series of openings therein, a receptacle secured in each opening and having a surface which is unattacked by the alkaline solution, both of the exposed walls of each receptacle being elastic and having numerous perforations permitting the passage of the solution therethrough, and an active material tightly packed in each receptacle, whereby the elastic walls of the latter will maintain continuous pressure with the active material, substantially as and for the purposes set forth.

2. A grid or plate for alkaline reversible galvanic batteries, the immersed surface of which is unaffected by the alkaline solution and having a series of openings therein, a receptacle made of telescoping sections secured in each opening and having a surface which is unattacked by the alkaline solution, both of the exposed walls of each receptacle being elastic and having numerous perforations permitting the passage of the solution therethrough, and an active material tightly packed in each receptacle, whereby the elastic walls of the latter will maintain continuous pressure with the active material, substantially as and for the purposes set forth.

3. A grid or plate for a reversible galvanic battery having a plurality of openings therein, a perforated cup or pocket the edges of which are crimped around the edges of each of the openings, and an active material in said cup or pocket, substantially as set forth.

4. A grid or plate for a reversible galvanic battery having a plurality of openings therein, a sectional perforated cup or pocket the edges of which are crimped around the edges of each of the openings, and an active material in said cup or pocket, substantially as set forth.

5. A grid or plate for a reversible galvanic battery having a plurality of openings therein, a perforated cup or pocket made of elastic metal and secured in place within each of said openings, and a coherent block of active material within each cup or pocket and maintained under pressure therein, substantially as set forth.

6. A grid or plate for a reversible galvanic battery having a plurality of openings therein, a perforated cup or pocket made of telescoping sections secured in place within each of said openings, and a coherent block of active material within each cup or pocket and maintained under pressure therein, substantially as set forth.

7. A plate or grid for a reversible galvanic battery employing an alkaline electrolyte and presenting an immersed surface of nickel, said plate having a series of openings therein, and a perforated cup or pocket within each of said openings and containing the active material, said cup or pocket being made of highly-elastic sheet metal having a nickel surface and of telescoping sections, substantially as set forth.

8. A plate or grid for a reversible galvanic cell employing an alkaline electrolyte, made of iron nickel-plated having a series of openings therein, and a perforated cup or pocket secured within each of said openings and containing the active material, said cup or pocket being made of nickel-plated sheet-steel and of telescoping sections, substantially as set forth.

9. A grid or plate for a reversible galvanic battery having a plu-

reality of openings therein, a perforated cup or pocket the edges only of which are crimped around the edges of each of the openings and the chamber of the cup or pocket being of less thickness at its marginal portions than at its other portions, and an active material in said cup or pocket, substantially as set forth.

10. A grid or plate for a reversible galvanic battery having a plurality of openings therein, a sectional perforated cup or pocket the edges only of which are crimped around the edges of each of the openings and the chamber of the cup or pocket being of less thickness at its marginal portions than at its other portions, and an active material in said cup or pocket, substantially as set forth.

11. As a new manufacture, a metallic cup or pocket made of telescoping sections having perforated walls, each perforation being surrounded by a bar of displaced metal which extends inwardly, and an active material within said cup or pocket, substantially as set forth.

700,188. CARD OR SHEET HOLDING ATTACHMENT FOR TYPE-WRITING MACHINES. ROBERT J. FISHER, Athens, Tenn., and HERMAN F. BOKHEIM, Cleveland, Ohio, assignors to the Fisher Type-Writer Company, Athens, Tenn. Filed Mar. 31, 1900. Serial No. 9,662. (No model.)

Claim.—1. In a type-writing machine, the combination with the flat platen, and the traveling printing mechanism, of work-holding members having guiding and holding means for the work, and interposed in a plane between the printing mechanism and the writing-surface of the platen, and mechanism comprising means located below the writing-surface of the platen for bodily shifting a work-holding member to provide for the internal adjustment of said members.

2. In a type-writing machine, the combination with the flat platen, and the traveling printing mechanism, of work-holding members having guiding and holding means for the work, and interposed in a plane between the printing mechanism and the writing-surface of the platen, and mechanism comprising means for bodily shifting and simultaneously adjusting a work-holding member.

3. In a type-writing machine, the combination with the flat platen, and the traveling printing mechanism, of work-holding members having guiding and holding means for the work, and interposed in a plane between the printing mechanism and the writing-surface of the platen, and mechanism comprising means for shifting and locking a work-holding member.

4. In a type-writing machine, the combination with the flat platen, and the traveling printing mechanism, of work-holding members having guiding and holding means for the work, and interposed in a plane between the printing mechanism and the writing-surface of the platen, and mechanism having means for shifting, and simultaneously adjusting and locking a work-holding member.

5. In a type-writing machine, the combination with the flat platen, and the traveling printing mechanism, of internally-movable work-holding members having guiding and holding means for the work, and interposed in a plane between the printing mechanism and the writing-surface of the platen, and mechanism comprising means for shifting, and simultaneously adjusting, said internally-movable members, said means being located below the writing-surface of the platen.

6. In a type-writing machine, the combination with the flat platen and the traveling printing mechanism, of shiftable work-holding members having guiding and holding means for the work, and interposed in a plane between the printing mechanism and the writing-surface of the platen, and mechanism comprising means for shifting, adjusting and locking said members, said means being located below the writing-surface of the platen.

7. In a type-writing machine, the combination with the flat platen, and the printing mechanism, of a work-holding member having guiding and holding means for the work, and interposed in a plane between the printing mechanism and the writing-surface of the platen, and adjusting mechanism comprising a rock-shaft having an operative connection with

the work-holding member to shift bodily the same laterally, and means for turning the rock-shaft in either direction.

8. In a type-writing machine, the combination with the flat platen, and the printing mechanism, of a laterally-movable work-holding member having guiding and holding means for the work, and adjusting mechanism comprising a rock-shaft having an operative connection with the work-holding member for shifting the same, operating means for turning the rock-shaft in either direction, and locking means for holding the shaft and the member associated therewith against movement.

9. In a type-writing machine, the combination with the flat platen, and the printing mechanism, of relatively movable work-holding members having guiding and holding means for the work, and adjusting mechanism including an actuating-spring which tends to normally vary the distance between the work-holding members in one direction, and means for adjusting the distance between said members in a direction contrary to the action of the spring.

10. In a type-writing machine, the combination with the flat platen, and the printing mechanism, of a movable work-holding member having guiding and holding means for the work, and adjusting mechanism comprising a rock-shaft having operative connection with the work-holding member to slide the same over the flat platen, an actuating-spring connected with the rock-shaft for normally turning the same in one direction, and an operating device also connected with said rock-shaft.

11. In a type-writing machine, the combination with the flat platen having slots therein, and the printing mechanism, of a movable work-holding member interposed in a plane between the printing mechanism and the writing-surfaces of the platen, said work-holding member having slide-blocks working in the slots of the platen, and adjusting mechanism comprising a rock-shaft having operative connection with said slide-blocks, and means for turning said rock-shaft in either direction.

12. In a type-writing machine, the combination with a movable work-holding guide, of a rock-shaft carrying swinging arms having link connections with the guide to provide for shifting the same laterally, an actuating-spring for turning the rock-shaft in one direction, an adjusting-head fitted to the rock-shaft and having an operating-handle, a locking device associated with the adjusting-head, and adjustable stops fitted to the adjusting-head, respectively at opposite sides of the locking device.

13. In a type-writing machine, the combination with the movable work-holding guide, of a rock-shaft carrying swinging arms having link connections with the guide to provide for shifting the same laterally, an actuating-spring for turning the rock-shaft in one direction, an adjusting-head fitted to the rock-shaft and having a segmental or screw slot, and a single operating-handle, a lock-throw working through the slot in said head and engaging a fixed point of support, and adjustable stop-bushes slidably mounted in the slotted adjusting-head, respectively at opposite sides of the said lock-throw.

700,189. ATTACHMENT FOR UTILITY PACKER. JOHN E. FULLER, Mansfield, Mass. Filed Jan. 2, 1902. Serial No. 34,000. (No model.)

Claim.—1. In combination with a surgical packer comprising a tube and a feeding-plunger for packing a strip of fabric into cavities, a packing-holder attached thereto having spring-arms which branch away from the tube and which are formed at the ends with long, pointed prongs

turned toward each other and adapted to penetrate the ends of a roll of packing formed of a strip wound close upon itself without any bobbin or spool, said prongs forming bearings on which the roll may rotate, said arms being formed of spring metal and adapted to be sprung apart to admit and to release the roll, substantially as described.

2. In combination with a surgical packer comprising a tube and a feeding-plunger for packing a strip of fabric into cavities, a packing-holder attached thereto having spring-arms which branch away from the tube and which are formed at the ends with long, pointed prongs turned toward each other and adapted to penetrate the ends of a roll of packing formed of a strip of fabric wound close upon itself without any bobbin or spool, said prongs forming bearings on which the roll may rotate, said arms being formed of spring metal and adapted to be sprung apart to admit and to release the roll of packing, and having one at the outer ends of the prongs, substantially as described.

3. In combination with a surgical packer comprising a tube and a feeding-plunger for packing a strip of fabric into cavities, a packing-holder comprising a sleeve whereby the holder may be mounted on said tube, means for clamping said sleeve to the tube, two arms secured in the sleeve and branching away from each other, the arms being turned in toward each other at their outer ends forming pointed prongs adapted to penetrate the ends of a roll of packing formed of a strip of fabric wound close upon itself without any bobbin or spool, said prongs forming bearings for the roll, the arms being formed of spring metal and adapted to be sprung apart in admit and to release the roll, substantially as described.

4. In combination with a surgical packer comprising a tube and a feeding-plunger, a packing-holder comprising a sleeve whereby the holder may be mounted on said tube, means for clamping the sleeve to the tube, two arms secured in the sleeve and branching away from each other, the arms having at their outer ends prongs which point toward each other and adapted to penetrate the ends of a roll of packing formed of a strip of fabric wound close upon itself without any spindle or spool, said prongs forming bearings for the roll, the arms being formed of spring metal, and adapted to be sprung apart to admit entrance of the roll and engagement by the prongs, and ears at the base of the prongs to guide and clamp the ends of the roll, substantially as described.

700,140. CAMERA. HANNAH GOODWIN, Newark, N. J.; Rebecca Goodwin executrix of said Hannah Goodwin, deceased. Filed Apr. 22, 1900. Serial No. 714,971. (No model.)

Claim.—1. The improved camera, herein described comprising a camera-box, provided with a suitable lens and a film-holder having therein pay-out roll and stripping means, the said stripping means being arranged to contact with the film, and effect a complete detachment of said film from its support, substantially as set forth.

2. The improved camera herein described, comprising a camera-box having an open diaphragm and a dark chamber, the mouth or entrance to which is disposed at or near the plane of said diaphragm, a stripping-blade outside of said mouth or entrance to the dark chamber and a film-holder having a pin and a spool-holder chamber back of said pin, substantially as set forth.

3. The improved camera herein described, comprising a camera-box, having a dark chamber and open diaphragm, a stripping-blade, a film-holder separable from the said box, and having a pin at the front an over-riding spool-holder at its free end adapted to be swung out from the spool-holder chamber to permit an easy manipulation of the spool therein, substantially as set forth.

4. The combination with the camera-box a, having a dark chamber, an open diaphragm and stripping-blade, of a film-holder adapted to be arranged in connection with said camera-box, the said film-holder having a removable plate adapted to be disposed parallel with the said open diaphragm and having a passage for the film therewith, the said plate terminating at one edge, short of the end of the film-holder to form a passage for the film and a spool adapted to be arranged in said film-holder, substantially as set forth.

5. In a camera, the combination with a camera-box having an open diaphragm, a dark chamber above said diaphragm and a stripping-blade, at the top of said diaphragm and adjacent to the mouth of the dark chamber, of a separable film-holder having a paten, adapted to lie parallel to said open diaphragm, said paten being recessed contiguous to the edge of the said stripping-blade to receive said edge and effect a flexing of the film in its passage to said blade, a supply-roller and a draft-roll at opposite ends of said paten, and means for fastening the said film-holder in the camera-box, substantially as set forth.

6. In a camera, the combination with the camera-box, having a dark chamber, open diaphragm, and stripping-blade, of a separable film-holder, having a spool, at the bottom of said open diaphragm and below the stripping-blade and adapted to contain the unexposed portions of the film and a drum above said open diaphragm and stripping-blade and adapted to receive one end of the film and, when turned, to effect an out-passage of the support of the said film and a stripping of the sensitive portion therefrom, substantially as set forth.

7. In a camera, the combination with the camera-box, its dark chamber, open diaphragm and stripping means of a roller for holding the unexposed film, breaking means therefor, and a drum or windlass for drawing the film over the said stripping-blade and means for preventing back movement of said drum or windlass, substantially as set forth.

8. In a camera, the combination with the camera-box, its dark chamber and stripping means, of a film-holder separable from said box, having a chamber for the unexposed film and a paten removable from said holder to permit manipulation of the spool-holder, and said spool-holder and means for holding it in place in said film-holder, substantially as set forth.

9. The combination with the camera-box having a dark chamber and stripping-knife, of a spring-actuated shutter for closing said dark chamber automatically and a drawing-in roll arranged within said dark chamber independent of the shutter, substantially as set forth.

10. The combination with the box, of a camera, having a dark chamber, of an automatic door at the mouth or entrance to said dark chamber and a drawing-in roll provided with teeth, and a spring for co-operating with said teeth, substantially as set forth.

11. The combination with the camera-box having the dark storage-chamber and stripping means, of a drawing device adapted to grasp the stripped portions after they have been detached and carry them into said dark chamber from the mouth or in-passage thereto, substantially as set forth.

12. In a camera, the combination with a film-supply spool, a stripping-blade, a paten between said spool and stripping-blade for exposing the film, a take-up spool beyond said stripping-blade for winding up the support or backing, a dark chamber having an entrance into which the stripped portion of the film is forced by the stripping operation an automatic door for said entrance, and means within the dark chamber for entirely drawing in the stripped portion of the film, substantially as set forth.

13. In a camera, the combination with the box having an open diaphragm, dark chamber and stripping-blade at the entrance to said dark chamber, of a film-holder having therein a swinging spool-holder comprising two springs between which the spool is held under friction, substantially as set forth.

14. In a camera, the combination with the box having an open diaphragm, dark chamber and stripping-blade, of a spool-holder consisting of springs providing bearings on which the spool is adapted to rotate, said springs pressing against the ends of said spool to retard turning, substantially as set forth.

15. In a camera, the combination with the box having an open diaphragm, dark storage-chamber for the light-improved film and a storage-chamber for the unimproved film and means in the latter chamber for holding the film, and the flexible supports therefor, said camera having a paten back of said diaphragm with a film-passage between said paten and the top of said passage, diverging passages, one leading into the dark storage-chamber and the other leading to the exterior of the camera, and stripping means at the junction of the passages, substantially as set forth.

700,141. **BUTTON-FLY-SCALLOPING MACHINE.** JAMES G. GRALL, DUBLIN, IRELAND, assignor, by means of assignment, to the Robert Mitchell Machinery Company, a Corporation of Michigan. Filed Jan. 8, 1898. Serial No. 701,312. (No model.)

Claim.—1. In a button-fly scalloper, the combination with a rotary table, and a vertically-reciprocating scalloping-knife above the table, of a separate guide-pattern adapted to carry the work in fixed relation thereto and projecting with its rear edge in rear of said work, a series of guide-marks on said exposed portion and a support for said guide-pattern on the table having a fixed guide mark or marks with which those of the guide-pattern are adapted to register separately and thereby position the work in relation to the knife.

2. In a button-fly scalloper, the combination with a table and a vertically-reciprocating scalloping-knife above the table, of a separate guide-pattern for the work adapted to support the same and having an exposed portion projecting in rear thereof, and guide-marks formed thereon, means in the guide-pattern for clamping the work thereon in a prescribed position, a support for the guide-pattern adjustably secured in front of said table and means on the guide-pattern and its support for positioning the guide-pattern upon the support in different prescribed positions.

3. In a button-fly scalloper, the combination with the frame and cutting-block supported thereon, of the vertically-reciprocating scalloping-knife, the separate guide-pattern provided with means for clamping the blank thereon, the series of notches cut into the front edge of the guide-pattern, and the pattern-guide support having a projection with which the notches on the guide-pattern are adapted to register.

4. In a button-fly scalloper, the combination with the frame and cutting-block supported thereon, of a vertically-reciprocating scalloping-knife, a separate guide-pattern for supporting the blank thereon and means for locating the guide in prescribed relation to the knife for each scallop, said guide-pattern having projecting lugs at the ends registering with the ends of the blank.

5. In a button-fly scalloper, the combination with the frame and rotary table supported thereon, of the reciprocating scalloping-knife adapted to cut portions of two adjacent scallops, the notched guide-pattern with which the blank is adapted to be registered having a series of guide-marks thereon, and the pattern-guide support having the projection and guide-mark.

6. In a button-fly-scalloping machine, the combination with an intermittent rotary cutting-block, and a vertically-reciprocating scalloping-knife, of a separate guide-pattern for carrying the blank, said guide-pattern having projections at its opposite ends registering with the ends of said blank, a fixed support for said guide-pattern in front of the cutting-block and means on the guide-pattern and its support for adjusting the guide-pattern in predetermined positions in relation to the knife to cut a series of connected scallops along one edge of the blank.

7. In a fly-scalloping machine, the combination with the frame of an intermittent rotary table having a cutting-block secured thereon, a vertically-reciprocating scalloping-knife, a separate guide-pattern for supporting the blank and with which the blank is adapted to be registered, an adjustable pattern-guide support for said guide-pattern in front of the table, a projection on said support, a series of notches on the guide-pattern adapted to be registered with said projection, a series of guide-marks on the pattern-guide, and a guide-mark on the support with which the above-said series of guide-marks are adapted to be registered.

700,142. **CURTAIN-HOLDER.** CHARLES HEYER, NEWARK, N. J., assignor of one-half to Jacob Fitzgerald, Newark, N. J. Filed Feb. 1, 1901. Serial No. 45,921. (No model.)

Claim.—1. The combination of a quadrangular frame-section having tubular side portions *S*, *S*, and top and bottom bars *T*, *B*, said section being perforated at the point of meeting of the side and bottom portions or bars in line with said side portions, a section having arms *A*, *A*, extending telescopically into said side portions, a curtain attached to said sections and adapted to be stretched thereon when said sections are fitted to the window, said curtain below the bottom bar *B*, being loosely attached to the arms of the lower frame-section to permit said arms to slide within the said side portions, means for holding said frame and curtain within the window-frame and means for holding the sections at the desired adjustment, substantially as set forth.

2. The combination with the window-frame, of a curtain holding and stretching frame constructed to fit the opening of said window, said frame being suspended from hooks attached to said frame and thus removably supported at the top, means for fastening said frame at the lower part, said frame being in sections, the lower one of which is adapted to be removed to permit access to the window and means for cutting one section with relation to the other, and a curtain attached to said frame-sections, the lower part being loosely attached to permit the sliding of the lower frame within the upper frame, substantially as set forth.

2. The combination with the window-frame, of a curtain holding and stretching frame constructed in fit the opening of said window, said frame being suspended from hooks attached in said frame, and then removably supported at the top, means for fastening said frame at the lower part, and shade-brackets attached to the upper part of said frame, said frame being in sections, the lower one of which is adapted to be moved to permit access to the window, and means for putting one section with relation to the other, the said frame and its shade-brackets permitting the swinging back of the stretched curtain and drawn-down shade without changing the relation of the shade and curtain to one another, substantially as set forth.

700,148. END-GATE FASTENER. ALBERT A. KILGUS, Clinton, Mo., assignor of one-half to Gustave C. Hayner, Clinton, Mo. Filed Mar. 14, 1900. Serial No. 93,999. (No model.)

Claim.—1. Is an end-gate fastening means of the character described, the combination with the wagon side, one of the said sides having the ordinary fixed end guide-chains, the other side having its end terminating in a plate with the outer face of the end-gate, and provided with a single fixedly-held inner cleat member; of the member 6 hinged to the outer edge of the wagon side, having the fixed cleat, and adapted to swing inwardly and beyond the inner face of the wagon-body side to which it is hinged, to form a guide portion for co-operating with the fixed cleat, the end-gate section having the stay portion 2, the rod 7, detachably connected at one end to the hinged member 6, adapted to extend across the end-gate and to bear against its cleat 3, and means on the wagon-body for drawing the said rod to a locking position, said means including a crank-shaft, adapted to be automatically held to its locked position by the strain on the rod 7, substantially as shown and described.

2. The combination with the wagon-body side 1^a 1^b, the cleats 3 3, fixedly secured to the side 1, the outer end of the side 1 and the cleats 3, being slotted horizontally, the fixed cleat 4, secured to the side 1^a, and the end-gate 2; of the member 6 hinged to the end of the side member 1^b, to close inward over the end of the said side member, and to project inwardly beyond the inner side of the member 1^a to form a cleat portion to co-operate with the fixed cleat 4, the rod 7, one end of which is adapted to play in the slot formed in the members 1 and 2, said rod 7 having a hook portion 7^a, adapted to detachably engage with the member 6, and the crank-shaft 8, having a pivotal engagement with the rod 7, and pro-

vided with a handle member for adjusting it, all being arranged substantially as shown and for the purposes described.

700,144. GOLF-BALL. BRADEN KNEFTHALL, Boston, Mass., assignor to The Knefthall Manufacturing Company, a Corporation of New Jersey. Filed Apr. 15, 1900. Serial No. 108,008. (No model.)

Claim.—1. A playing-ball comprising a wear-resisting cover and a distorted core of soft rubber held under compression thereby; said core being distorted throughout in radial directions.

2. A playing-ball comprising a solid rubber spherical shell and a cover of hard, wear-resisting material thereon; said rubber shell being in a state of collapse and held under compression by said casing.

3. A playing-ball comprising a cover of plastic material and a filling held under compression thereby; said filling consisting of a solid-rubber spherical shell in a state of collapse.

4. A playing-ball comprising a cover which consists of welded segments of gutta-percha, and a filling held under compression by said shell; said filling consisting of a rubber spherical shell in a state of collapse but tending constantly to recover its normal form.

5. A playing-ball comprising a rubber spherical shell in a state of collapse, and a cover holding said shell under compression; said cover being a compound of plastic material and fabric.

6. A playing-ball comprising a cover of plastic material and a filling held under compression thereby; said filling consisting of a solid-rubber spherical shell which is collapsed to such an extent as to form substantially a solid sphere.

7. A playing-ball comprising a cover consisting of welded segments of plastic material, and a filling held under compression by said shell; said filling consisting of a rubber spherical shell collapsed to such an extent as to form a substantially solid sphere.

8. A playing-ball comprising a cover consisting of welded segments of gutta-percha, and a filling held under compression by said shell; said filling consisting of a rubber spherical shell collapsed to such an extent as to form a substantially solid sphere.

9. A playing-ball comprising a rubber spherical shell compressed to an extent to form a solid sphere, and a covering upon said sphere consisting of plastic material compounded with fabric.

10. A playing-ball comprising a wear-resisting cover and a distorted core of soft rubber held under compression thereby; said core being distorted throughout in radial directions, and forming a solid sphere.

11. A playing-ball comprising a rubber sphere compressed in bulk and a shell thereon consisting of plastic material and fibrous material, the latter being continuously wound in different directions and embedded in the plastic material.

12. A playing-ball comprising a rubber sphere compressed in bulk, and a shell thereon, said shell comprising welded segments of plastic material and a casing, the latter consisting of plastic material in which are embedded strips of fabric, and said strips being wound continuously in different directions.

13. A playing-ball comprising a rubber sphere materially compressed in bulk, and a shell holding said sphere under compression; said shell including portions of gutta-percha and fabric.

14. A playing-ball comprising a rubber sphere materially compressed in bulk, and a shell holding said sphere under compression; said shell comprising gutta-percha, fabric and collodion, the latter forming the periphery or lining of the ball.

15. A playing-ball comprising a rubber sphere materially compressed in bulk, a shell holding said sphere under compression, said shell consisting of welded segments of gutta-percha, and a casing consisting of strips of collodion and fabric wound continuously in different directions and compressed upon said gutta-percha.

16. A playing-ball comprising a springy core, a gutta-percha shell thereon, and a casing on said shell; said casing consisting of strips of collodion and fibrous material wound continuously in different directions and welded together where they cross.

17. A playing-ball comprising a soft-rubber sphere, a gutta-percha shell thereon, and a casing upon said shell consisting of strips of collodion wound continuously in different directions and welded together where crossing; fibrous material being embedded throughout said casing.

18. A playing-ball comprising a soft-rubber sphere, a gutta-percha shell thereon, and a casing upon said shell; said casing consisting in strips compounded of plastic material and fibrous material wound continuously in different directions upon said gutta-percha and welded where crossing, and said casing and gutta-percha shell being highly compressed.

19. A playing-ball comprising a core, segments of plastic material welded together upon said core, and a casing upon said segments consisting of plastic material throughout which ligaments are embedded.

700,145. CONICAL-ROLLER BEARING. JOSHUA R. LARSEN, JAMES L. PARKER, and JAMES A. JOYCE, Cleveland, Ohio. Filed Jan. 24, 1901. Serial No. 44,998. (No model.)

Claim.—1. In a roller-bearing, the combination of a lower section having an inclined wearing-surface and an annular upwardly-extending flange, an upper section having a wearing-surface inclined in the reverse direction to the wearing-surface of the lower section, said upper section having a downwardly-extending annular flange which incloses the upper portion of the flange of the lower section, a series of conical bearing-rollers arranged on the wearing-surface of the lower section and engaged by the wearing-surface of the upper section, a pin loosely mounted in central recesses provided therefor in the lower face of the upper section and upper face of the lower section respectively, a center ring carried by said pin and circumferentially recessed on its undermost face to receive transmissions on the inner ends of the central rollers, a rotative ring having apertures to receive transmissions on the outer ends of the conical rollers, and antifriction-bearings between the ends of the rollers and the rotative ring, substantially as described.

2. In a roller-bearing, the combination of a lower section having a wearing-surface and an upwardly-extending annular flange, an upper section having a wearing-surface and a downwardly-extending annular flange that surrounds the upper portion of the flange of the lower section, said upper section having a central oil-aperture, a series of circumferentially-arranged conical bearing-rollers engaged by the wearing-surfaces of the sections, a pin fitted in central recesses provided therefor in the lower face of the upper section and upper face of the lower section, a center ring mounted on said pin to receive transmissions on the inner ends of said rollers, grooved bearing-rings in said rotative ring and in the outer ends of the rollers, and antifriction-bearings in said grooved bearing-rings, substantially as described.

700,146. TURRET-LATCH. JAMES P. LAYTON, New Haven, Conn., assignor to Standard Screw Co., Chicago, Ill., a Corporation. Filed Mar. 13, 1901. Renewed Jan. 24, 1902. Serial No. 91,008. (No model.)

Claim.—1. In a turret-latch, the combination with the turret thereof, of means for imparting step-by-step rotary movement thereto, a locking-bolt for the turret, a bolt-retracting lever for operating the said bolt in unlatching the turret, a drum, and pins mounted in the said drum and coacting with the said lever and with the said rotating means which are arranged so that each pin operates successively upon the lever and then upon the said rotating means.

2. In a turret-latch, the combination with the turret thereof, of means for imparting step-by-step rotary movement thereto, including a star-wheel, a locking-bolt for the turret, a bolt-retracting lever provided with an arm, a drum, and pins mounted in the drum and coacting with the said arm of the said lever for retracting the bolt and unlatching the turret, and then coacting with the star-wheel for the rotation of the turret when so unlatched.

3. In a turret-latch, the combination with the turret thereof, of means for imparting step-by-step rotary movement thereto, including a star-wheel, a locking-bolt for the turret, a bolt-retracting lever provided with an arm formed upon its under face with a bevel and with a flat containing-surface, a drum, and pins mounted in the drum and coacting with the said arm of the lever for retracting the bolt and unlatching the turret, and then coacting with the star-wheel for the rotation of the turret.

4. In a turret-latch, the combination with the turret thereof, of a turret-slide formed with a deep groove, a turret-locking bolt located in the said groove, means for operating the said bolt, two tapering pins located

in the said groove upon opposite sides of the said bolt, supporting-curves mounted in the said pins, projecting below the lower edges thereof and resting upon the bottom of the said groove in which the pins are raised or lowered by means of the said curves, and pressure-curves mounted in the said slide and engaging with the pins for forcing the same laterally inward and holding them in place.

5. In a turret-latch, the combination with the main shaft thereof, of cutting instrumentalities driven by the said shaft, and differential gearing connected with the said shaft for driving the same at varying rates of speed, the said differential gearing including a revolving cup arranged in a vertical plane, a plurality of gears located within the said cup, an annular cap applied to the open end of the cup which it converts into an oil-retaining cup, and one or more studs mounted in the cup and extending through the said cup which they hold in place and which in turn assist in supporting the said studs.

700,147. SPARKING PLUG. CHARLES A. MEYER, Brooklyn, N. Y., assignor to Electric Motor, Brooklyn, N. Y. Filed Mar. 25, 1902. Serial No. 93,982. (No model.)

Claim.—1. The combination of a chambered plug having a sparking point thereon, an elongated conducting member forming the second sparking point and projected through the chamber and extending adjacent to the sparking point, and a tubular shell arranged in the chamber of the plug and spaced from the walls thereof and from the sides of said elongated member forming the second sparking point, for the purpose specified.

2. The combination of a chambered plug having a sparking point thereon, an elongated conducting member projected through the chamber and extending adjacent to the sparking point, a tubular insulating-shell arranged in the chamber of the plug and spaced from the walls thereof and from the sides of said elongated member forming the second sparking point, for the purpose specified, an insulating-tube at the base of the insulating-shell, and means for holding the said elongated conducting member snugly within the shell and tube.

3. The combination of a chambered plug having a sparking point

thereon, an elongated insulating member projected through the chamber and extending adjacent to the sparking point, a tubular shell arranged in the chamber of the plug and spaced from the walls thereof and from the sides of said elongated member forming the second sparking point, for the purpose specified, an insulating-tube at the base of the said insulating-shell, and means for holding the said elongated conducting member snugly within the shell and tube, said means comprising an insulated cap bearing against the plug and a nut working on the outer end of the said elongated conducting member.

4. An electric igniter, comprising an elongated member forming a sparking point, and an insulating-shell enclosing the major portion of the exposed part of said elongated member, the said shell having an open space around its outer side and between its inner side and the said elongated member.

5. The combination of a plug proper having a chamber therein and a reduced passage leading therefrom, an insulating-tube placed in the said passage and having a shell-like extension projected into the chamber of the plug and spaced from the interior walls thereof, and a rod projected through the tube and through the shell, said rod being spaced from the inner walls of the shell, for the purpose specified.

6. The combination of a plug proper having a chamber therein and a reduced passage leading therefrom, an insulating-tube placed in the said passage and having a shell-like extension projected into the chamber of the plug and spaced from the interior walls thereof, a rod projected through the tube and through the shell, said rod being spaced from the inner walls of the shell for the purpose specified, and being formed with an enlargement engaging a shoulder at the outer end of the shell, and means for exerting an outward pressure on the rod to hold the parts snugly engaged.

700,148. AUTOMATIC CREAM-COOLER. MARTIN E. MILLER, Omaha, Neb. Filed Feb. 12, 1902. Serial No. 98,712. (No model.)

Claim.—1. The combination with a suitable trough having an outlet, of a tank held within said trough, a water-receptacle above said tank, a siphon extending from said receptacle and emptying into said trough, a float within said water-receptacle, a cooling-coil secured to said float, one end of said cooling-coil being in connection with a suitable intake, the remaining end connected to said water-receptacle.

2. The combination with a trough, of a tank held within said trough, an exit-pipe extending from said trough, a drain-cock secured to said tank, a water-receptacle secured above said tank, a siphon extending from said water-receptacle and entering said trough, a cooling-coil within said tank both ends extending upward, one terminating in a goose-neck connected to said water-receptacle, the remaining end being in connection with the water-supply, and a float within said water-receptacle secured by means of brackets to said cooling-coil, all arranged substantially as and for the purpose set forth.

700,149. ANTICLIPPING HOOF-PAD. JOHN E. MITCHELL, Washington, D. C., assignor of one-half to Mary E. Emery, Mary A. Emery, and William Van Zandt Cox, executors and trustees of Matthew S. Emery, deceased. Filed Sept. 26, 1901. Serial No. 78,992. (No model.)

Claim.—1. An anticlipping hoof-pad, comprising a fitted oblong body, keepers fastened to the upper surface of the pad and having rearwardly-diverging adjacent edges, and a retaining-spring fastened between

the keepers and body of the pad with its extremities projecting beyond the ends of the pad, said spring allowing the pad to project below the horse's hoof, substantially as and for the purpose specified.

2. An anticlipping hoof-pad, comprising a fitted body, keepers applied to the upper surface of the body of the pad, a retaining-spring interposed between the keepers and pad and arranged to permit the pad to project below the horse's hoof, and fasteners passing through the keepers and pad and serving to secure the keepers to the pad and also serving to secure the spring between the keepers and pad.

3. An anticlipping hoof-pad, comprising a fitted body, keepers applied to the upper surface thereof, a retaining-spring held between the keepers and pad and arranged to permit the pad to project below the horse's hoof, fasteners which serve to secure the keepers to the pad and hold the spring between the keepers and pad, said fasteners being inserted through the keepers and pad and clamped against the bottom of the pad, and flange-strips connected to the bottom of the pad and covering the clamped portions of the fasteners.

700,150. POWER-INDICATOR. HERMAN MÜLLER, Leipzig, Germany. Filed Jan. 12, 1902. Serial No. 10,077. (No model.)

Claim.—1. A power-indicator, comprising a shaft to be driven, a hub on the same, a pulley and a plurality of spiral springs which are connected at their outer ends with the rim of the pulley, and at their inner ends with the hub in such a manner that the locations of the centers of gravity of the springs are equalized relatively to the axis of rotation, substantially as set forth.

2. A power-indicator, comprising a driven shaft, a hub on said shaft, a pulley and a plurality of spiral springs, the outer ends of which are connected with the pulley at diametrically opposite points, and the inner ends thereof are connected at diametrically opposite points with the hub at an angle of ninety degrees relatively to the outer ends so that the locations of the centers of gravity of the springs are equalized relatively to the axis of rotation, substantially as set forth.

700,151. MOTOR-CYCLE. WILLIAM E. EMERY, Dayton, Ohio. Filed Mar. 24, 1902. Serial No. 99,506. (No model.)

Claim.—1. The combination with a motor including a laterally-movable hollow crank-shaft and a pitman, of a pedal crank-shaft formed in two sections which are connected through the path of the pitman so that a movement of one section will result in a corresponding movement of the other section, brake members mounted respectively on the laterally-movable hollow crank-shaft and a stationary part of the motor, and means for moving the hollow crank-shaft laterally when the pedal crank-shaft is moved backward by either pedal.

2. The combination with a motor including a laterally-movable crank-shaft, of a pedal crank-shaft concentric therewith, means controlled by the pedal crank-shaft for moving the motor crank-shaft laterally, exhaust-valve gear, make-and-break mechanism for controlling the spark, and means operated by the lateral movement of the crank-shaft for preventing the seating of the exhaust-valve and for breaking the circuit.

3. The combination with a cycle, of a motor, a driving-pedal crank-shaft, means for applying a brake to the motor controlled from the pedal crank-shaft, exhaust-valve gearing, make-and-break mechanism for controlling the spark, and means controlled by the pedal crank-shaft for preventing the seating of the valve and breaking the circuit.

4. The combination with a cycle, of a motor, means connecting the motor and the driving-wheel, a pedal crank-shaft, means connecting this latter shaft and the driving-wheel, a brake for the driving-wheel controlled from the pedal crank-shaft and a brake for the motor also controlled by said shaft.

5. The combination with a vehicle, of a motor, a starting crank-shaft independent of the motor but passing through the crank-shaft of the same and also through the path of travel of the motor crank-shaft.

6. The combination with a motor having a crank and pitman, of an independent crank-shaft and connections passing through the path of travel of the motor-crank and pitman.

7. The combination with a motor having a crank, pitman and fly-wheel, of an independent crank-shaft and connections passing through the path of travel of the motor-crank, pitman and fly-wheel.

8. The combination with a motor having a double crank and a pitman, of an independent crank-shaft and connections passing through the path of travel of the crank and pitman.

9. The combination with a motor including two fly-wheels connected by a pin to form the crank, of an independent crank-shaft and connections passing through the path of travel of the motor-crank.

10. The combination with a motor including a crank-shaft and a pitman, of an independent crank-shaft concentric with the first crank-shaft and formed in separated sections, and means connecting the sections through the path of movement of the crank and pitman.

11. The combination with a motor having a crank and crank-shaft formed of hollow shaft-sections, fly-wheels and a connecting-pin, of independent crank-shaft sections passing through the hollow sections and means connecting the independent sections through the path of travel of the crank.

12. In a motor-cycle including a motor and a starting and controlling pedal-shaft the combination of a brake forming part of the motor and controlled entirely from the pedal.

13. In a motor-cycle including a motor and a starting and controlling pedal-shaft, valve-gear operated by the motor, and means operated by the pedal-shaft for preventing the motor, when running, from feeding fuel.

14. In a motor-cycle including a motor and a starting and controlling pedal-shaft, the combination with make-and-break devices for the circuit controlling the spark, of means operated by the pedal-shaft for breaking the circuit.

15. The combination of a motor having a crank-shaft, of a pedal crank-shaft concentric therewith and formed in two sections, and means connecting the two sections so that they move together without interfering with the motor crank-shaft.

16. The combination of a motor having a crank-shaft made up of hollow shaft-sections, fly-wheels and a crank-pin, of pedal-shaft sections mounted within the hollow shaft-sections and means for connecting the pedal-shaft sections so that they move together.

17. The combination of a motor having a crank-shaft, a pedal crank-shaft concentric therewith and formed in two sections, and gearing connecting these sections through the path of the motor crank-shaft.

18. In a motor-cycle the combination with a diamond frame, of a driving-wheel journaled at the rear point of the diamond, a motor hung at the lower point of the diamond, and a pedal-shaft hung at the same point.

19. The combination with a motor including two fly-wheels connected by a crank-pin to form the motor-crank, of a pitman connected to the crank-pin, and an independent crank-shaft concentric in the motor

crank-shaft and including connections which pass through the path of the motor crank-shaft and pitman.

20. In a motor-cycle the combination with a frame, of a driving-wheel, a motor so located in the frame that the rear fork of the latter extends in a direct line between the motor crank-shaft and the driving-wheel axle, and a controlling pedal crank-shaft so mounted as to bear a similar relation to the rear fork.

21. In a motor-cycle the combination with a frame, a driving-wheel, a motor, a brake for the driving-wheel, a direct brake for the motor, a pedal crank-shaft, and means for controlling both brakes from the pedal crank-shaft.

22. In a motor-cycle the combination with a motor, of a cycle driving-wheel, a brake for the driving-wheel, make-and-break devices, and a pedal crank-shaft, connections between said shaft and brake, and means controlled by said shaft for preventing the motor feeding fuel and for breaking the electric circuit.

23. In a motor-cycle the combination with a motor, of a pedal crank-shaft and means intermediate the shaft and motor for preventing explosions in the motor at will.

24. In a motor-cycle the combination with a motor, of a pedal crank-shaft, and means intermediate the shaft and motor for preventing the opening of the exhaust-valve at will.

25. In a motor-cycle the combination with a motor, of a pedal crank-shaft and means intermediate the shaft and motor for preventing the sparking in the motor at will.

26. In a motor-cycle the combination with a motor, of a pedal crank-shaft, a direct brake for the motor and means intermediate the crank-shaft and brake for applying the same to the motor at will.

27. The combination with a motor including a crank-shaft of an independent shaft formed in two sections and mounted concentric with the crank-shaft, a sleeve mounted on the crank-pin and provided with gears and gears connecting the shaft-sections and said sleeve-gears so that the two shaft-sections move together.

28. The combination with a motor including a crank-shaft having hollow journal-sections, of an independent shaft formed in two sections which are mounted respectively in the hollow shaft-sections, a sleeve mounted on the crank-pin and carrying gears at its opposite ends and gears connecting the independent shaft-sections to the sleeve-gears.

29. The combination with a motor including a crank-shaft made up of two fly-wheels, a connecting crank-pin, and hollow journal-sections, of an independent pedal crank-shaft formed in sections and mounted in the hollow motor crank-sections, gears mounted on the pedal crank-sections, a sleeve on the crank-pin carrying gears which mesh with the sleeve-gears and a pitman with its lower end journaled on said sleeve.

30. The combination with a motor having incoiled crank and fly wheels, of a brake within the motor and applied directly to the crank-shaft, and means for operating the brake from the exterior of the motor.

31. The combination of a motor having incoiled fly-wheels, of friction-brake members mounted respectively upon the fly-wheels and the crank-casing and means for bringing the members together from the exterior of the casing.

32. The combination with a motor having a laterally-movable crank-shaft, of a brake mounted upon said shaft and brought into action by its lateral movement, and means for moving the shaft laterally.

33. The combination with a motor, of a starting-shaft for the same and means for arresting the motor when the shaft is moved backward.

34. In a motor-vehicle the combination with an explosive-motor, of a crank-shaft for starting the same, and means connected to said shaft for preventing the motor sparking when the shaft is moved backward.

35. In a motor-vehicle the combination with a motor, of a lever for starting the same, and means connected to the lever for preventing fuel being fed to the motor when said lever is moved backward.

36. In a motor-vehicle the combination with a motor, of a starting-crank, a direct brake for the motor and means connecting the crank and brake for applying the latter when the crank is moved backward.

37. In a motor-vehicle the combination with a motor, of a starting-crank for the same and means for cutting off the supply to the motor and breaking the circuit when the crank is turned backward.

38. In a motor-vehicle the combination with a motor, of a starting-crank, means intermediate the crank and motor for moving the latter forward with the crank for allowing the latter to remain stationary or move backward independently, and means for preventing explosions in the motor when the crank is moved backward.

39. The combination with a motor, of a starting crank-shaft for the same concentric with the motor crank-shaft and means intermediate the starting crank-shaft and the motor crank-shaft for communicating movement to the latter.

40. The combination with a motor, of a starting crank-shaft for the same concentric with the motor crank-shaft and means for preventing explosions in the motor controlled by the starting crank-shaft.

41. In a motor-vehicle the combination with a motor of a starting-crank for the same and means controlled by the starting-crank for preventing or allowing explosions in the motor.

42. In a motor-vehicle the combination with an explosive-motor, of means for starting said motor, and devices actuated by the starting means for controlling the explosions in the motor.

43. In a motor-vehicle the combination with an explosive-motor, of a starting means and connections for controlling the speed of the motor.

44. In a motor-vehicle the combination with an explosive-motor, of a manually-operated starting means, and devices actuated by said means for controlling the speed of the motor.

45. In a motor-cycle the combination with an explosive-motor, of a pedal crank-shaft for starting said motor and devices actuated by said crank-shaft for controlling the speed of the motor.

46. In a motor-cycle the combination with an explosive-motor, of a pedal crank-shaft for starting said motor and means actuated by said pedal-shaft for breaking the electric circuit and thus preventing sparking in the motor.

47. In a motor-cycle the combination with an explosive-motor, of a pedal crank-shaft for starting both the cycle and the motor and means actuated by said shaft for controlling the speed of the motor.

48. In a motor-cycle the combination with a motor having a crank-shaft made up of shaft-sections carrying each a fly-wheel and a crank-pin connecting said fly-wheels, of a pedal crank-shaft formed of two sections concentric with the motor crank-shaft sections, gears mounted on the inner ends of the pedal-crank-shaft sections and a sleeve journaled on the crank-pin and carrying gears at its opposite ends which mesh with the sleeve-gears.

49. In a motor-vehicle the combination with a motor having a laterally-movable crank-shaft, of a brake applied to the motor by the lateral movement of said shaft and means for moving the shaft laterally at will.

50. In a motor-vehicle the combination with a motor having a laterally-movable crank-shaft, and a starting device for the motor also controlling the lateral movement of the shaft.

51. In a motor-vehicle the combination with a motor having a laterally-movable crank-shaft, means for moving the shaft laterally at will, and speed-controlling devices actuated by the lateral movement of the shaft.

52. In a motor-cycle the combination with a motor, of a driving-wheel, a pedal crank-shaft, a counter-brake on the driving-wheel, means connecting the pedal crank-shaft and counter-brake, a direct brake for the motor also controlled by the pedal crank-shaft, and means connecting the motor and driving-wheel.

700,152. CAR-LOADER. RALPH E. RUTHERFORD, Starting, II. Filed Apr. 10, 1901. Serial No. 64,222. (No model.)

Claim.—1. In a car-loader, the combination with a driving-shaft, of a main frame pivotally mounted on said driving-shaft to swing in a vertical plane, a supplemental frame slidably supported on said main frame, a horizontally-disposed rotary distributing device carried by said supplemental frame and a telescopic shaft geared to the driving-shaft and operating the distributing device, substantially as described.

2. In a car-loader, the combination with a driving-shaft, of a main frame pivotally mounted on said shaft to swing in a vertical plane, parallel hollow shafts carried by the main frame and geared to said driving-shaft, a supplemental frame slidably supported on said main frame, a horizontally-disposed rotary double-cylinder distributor carried by said supplemental frame, and shafts for operating said distributor and telescoping in said hollow shafts, substantially as described.

3. In a car-loader, the combination with a driving-shaft, of a main frame pivotally mounted on said shaft to swing in a vertical plane, a supplemental frame slidably supported on said main frame, a horizontally-disposed rotary distributing device carried by said supplemental frame, a telescopic shaft geared to the driving-shaft and operating the distributing

device, and means for swinging the frame from a horizontal to a vertical position, substantially as described.

700,153. CAR-LOADER. RALPH E. RUTHERFORD, Starting, II. Filed Apr. 10, 1901. Serial No. 64,223. (No model.)

Claim.—1. In a car-loader, a distributing device comprising a cylinder and a discharge-spout connected with said cylinder on its periphery by a hinged joint and adjustable in an opening therein, substantially as described.

2. In a car-loader, a distributing device comprising a cylinder and a discharge-spout hinged at one end to the periphery of the cylinder and having its bottom curved to correspond with the periphery of the cylinder, substantially as described.

3. In a car-loader, a distributing device comprising a cylinder, a discharge-spout hinged on the periphery of said cylinder and adjustable in an opening therein, said spout consisting of a curved bottom and straight sides arranged to be adjusted within the sides of the cylinder, substantially as described.

4. In a car-loader, a distributing device comprising a cylinder, and oppositely-arranged discharge spouts hinged on the periphery of said cylinder and adjustable in openings therein, substantially as described.

5. In a car-loader, the combination with a driving-shaft, of a distributing device mounted thereon and comprising a cylinder provided with receiving-openings on opposite sides of the driving-shaft, oppositely-arranged discharge-spouts hinged on the periphery of said cylinder and adjustable in openings therein, swinging covers for the side receiving-openings, and a spider mounted on the shaft within the cylinder and provided with blades operating therein, substantially as described.

700,154. MANUFACTURE OF GOLF-BALLS. FRANK H. RUSSELL, Hartford, Conn., assignor to The Russell Manufacturing Company, a Corporation of New Jersey. Filed Mar. 17, 1902. Serial No. 64,224. (No model.)

Claim.—1. A process in producing playing-balls, consisting in incasing a hollow sphere of rubber in a gutta-percha casing and then forcing a fluent mass into said sphere.

2. A process in producing playing-balls, consisting in covering a yielding sphere with a casing of gutta-percha, forcing a fluent mass into the interior of said sphere and hardening said mass to form a core.

3. A process in producing playing-balls, consisting in covering a hollow sphere of soft rubber with a gutta-percha casing, reducing material to a fluent condition, forcing it into said sphere so as to expand the latter, and causing said material to harden so as to form a core.

4. A process in producing playing-balls, consisting in incasing a soft-rubber envelop in gutta-percha, and expanding both envelop and casing by the injection of molten material into the latter.

5. A process in producing playing-balls, consisting in providing a rubber sphere with a gutta-percha casing, injecting heated gutta-percha into said casing, and causing said injected gutta-percha to harden and form a core.

6. A process in producing a playing-ball, consisting in providing a highly-yielding sphere with a casing of gutta-percha, heating said casing, injecting plastic material into said sphere to an extent to expand both said sphere and said casing, causing said sphere during such injection so as to determine the shape of the ball, and causing said injected material to harden and form a core.

7. A process in producing a playing-ball, consisting in providing a hollow elastic sphere with a gutta-percha casing, forcing plastic material into said sphere to such an extent as to expand both said sphere and said casing and cause said sphere to be compressed between said injected material and said casing, and maintaining the pressure upon said injected material until both the casing and the injected material harden.

8. A process in producing a playing-ball, consisting in heating a rubber sphere with gutta-percha, placing the ball thus formed in a mold, heating the gutta-percha casing, and forcibly injecting molten material into said sphere to an extent to compress the gutta-percha casing and place said sphere under compression between said injected material and said casing.

9. A process in producing a playing-ball, consisting in including a hollow rubber sphere in a casing of gutta-percha, including said casing in a larger mold, forcibly injecting fluid material into said sphere to an extent to expand both said sphere and said casing to the limits of the mold, and also to compress said sphere between said injected material and said casing, and hardening said casing and said injected material while the pressure upon the latter is maintained.

10. A process in producing a playing-ball, consisting in loosely including a hollow rubber sphere in a casing consisting of at least partially of gutta-percha, including said casing loosely in a larger mold, forcibly injecting heated gutta-percha into said sphere to an extent to expand both said sphere and said shell to the limits of said mold, and maintaining the pressure upon said gutta-percha casing until both the latter and said casing become hard.

11. A process in producing a playing-ball, consisting in forming a hollow soft-rubber sphere with a vent, heating said sphere in a gutta-percha casing also provided with a vent, inserting a funnel through said casing and into said sphere, including said casing in a larger mold, heating said casing, heating gutta-percha, injecting said gutta-percha through said funnel into said sphere and forcing out the air through said vent, subjecting the gutta-percha to pressure to an extent to expand both said sphere and said casing to the limits of the mold, preventing the escape of gutta-percha through said vent during the application of pressure, causing the gutta-percha and the gutta-percha casing both to harden while the pressure is maintained, withdrawing the funnel, and plugging the vent.

700,155. MANUFACTURE OF GOLF-BALLS. FRANK E. KIMBALL, Hartford, Conn., assignor to the Kimball Manufacturing Company, a Corporation of New Jersey. Filed Mar. 17, 1898. Serial No. 18,567. (No model.)

Claim.—1. A process in producing playing-balls, consisting in including a hollow sphere of rubber in a harder shell and then forcing a fluent mass into said sphere.

2. A process in producing playing-balls, consisting in covering a yielding sphere with a shell of plastic material, forcing a fluent mass into the interior of said sphere and hardening said mass to form a core.

3. A process in producing playing-balls, consisting in covering a hollow sphere of soft rubber with a shell, reducing material to a fluent condition, forcing it into said sphere so as to expand the latter, and causing said material to harden so as to form a core.

4. A process in producing playing-balls, consisting in providing a soft-rubber envelope with a plastic shell, and expanding said envelope and shell by the injection of molten material.

5. A process in producing playing-balls, consisting in providing a rubber sphere with a plastic shell, injecting heated gutta-percha into said envelope, and causing said gutta-percha to harden and form a core.

6. A process in producing a playing-ball, consisting in providing a highly-yielding sphere with a shell of plastic material, heating said shell, injecting plastic material into said sphere to an extent to expand both said sphere and said shell, causing said sphere during such injection so as to determine the shape of the ball, and causing said injected material to harden and form a core.

7. A process in producing a playing-ball, consisting in providing a hollow elastic sphere with a shell, forcing plastic material into said sphere to such an extent as to expand both said sphere and said shell and cause said sphere to be compressed between said injected material and said shell, and maintaining the pressure upon said injected material until both the shell and the injected material harden.

8. A process in producing a playing-ball, consisting in heating a rubber sphere with celluloid, placing the ball thus formed in a mold, heating the celluloid, and forcibly injecting molten material into said sphere to an extent to compress the celluloid and place said sphere under compression between said injected material and said shell.

9. A process in producing a playing-ball, consisting in including a hollow rubber sphere in a shell of celluloid, including said shell in a larger mold, forcibly injecting fluent material into said sphere to an extent to expand both said sphere and said shell to the limits of the mold, and also to compress said sphere between said injected material and said shell, and hardening said shell and said injected material while the pressure upon the latter is maintained.

10. A process in producing a playing-ball, consisting in including a hollow rubber sphere in a plastic shell, including said shell in a larger mold, forcibly injecting heated gutta-percha into said sphere to an extent to expand both said sphere and said shell to the limits of the mold, and causing said shell and said injected material to harden while the pressure upon the latter is maintained.

11. A process in producing a playing-ball, consisting in loosely including a hollow rubber sphere in a shell consisting of at least partially of celluloid, including said shell loosely in a larger mold, forcibly injecting heated gutta-percha into said sphere to an extent to expand both said sphere and said shell to the limits of said mold, and maintaining the pressure upon said gutta-percha shell until both the latter and said shell become hard.

12. A process in producing a playing-ball, consisting in forming a hollow soft-rubber sphere with a vent, heating said sphere in a celluloid shell also provided with a vent, inserting a funnel through said shell and into said sphere, including said shell in a larger mold, heating said shell, heating gutta-percha, injecting said gutta-percha through said funnel into said sphere and forcing out the air through said vent, subjecting the gutta-percha to pressure to an extent to expand both said sphere and said shell to the limits of the mold, preventing the escape of gutta-percha through said vent during the application of pressure, causing the gutta-percha and the celluloid shell both to harden while the pressure is maintained, withdrawing the funnel, and plugging the vent.

700,156. DRAFTSMAN'S SCALE. ROBERT J. BROWN, Athol, Mass., assignor to The L. S. Starrett Company, Athol, Mass., a Corporation of Massachusetts. Filed Apr. 5, 1900. Serial No. 11,568. (No model.)

Claim.—1. The improved sliding scale, comprising the body A having a middle portion graduated at the edges, and blank or ungraduated portions at the ends, and the slide B projecting centrally and equidistantly from said blank portions at each end of said scale, substantially as set forth.

2. The draftsman's sliding ruler or scale comprising a flattened body having a central graduated portion and blank or ungraduated portions at the ends, and transverse studs not in perforations in said blank portions and extending laterally and equidistantly therefrom on each side of said ruler, substantially as set forth.

3. A draftsman's ruler or scale comprising a flattened body having an intermediate portion graduated at the edges and a blank or ungraduated space at each end, and transverse studs passing through central perforations in said ungraduated spaces and extending laterally upon each side of said ruler, to support the same in an inclined position, substantially as set forth.

4. A draftsman's sliding ruler or scale, comprising a flattened body

having graduated edges and perforated at each end midway between said edges, and with rigid supporting studs or pins inserted in each perforation and extending outwardly on each side of said body to a distance equal to about half the width of the ends, so as, when used either side up, to maintain either edge in contact with the work by gravity, substantially as set forth.

700,157. WELLSHOOT OR OTHER INCANDESCENT BURNER. THOMAS J. BURR, Philadelphia, Pa., assignor to Wellschoot Light Company, Gloucester City, N. J., a Corporation of New Jersey. Filed Nov. 18, 1891. Serial No. 25,394. (No model.)

Claim.—1. The combination in an incandescent burner of a rigid support, a flat spiral spring having its outer convolution attached to said support, a weighted burner-head supported and carried by the inner convolution of the spring, and a connection for supplying gas to said burner-head, substantially as described.

2. The combination in an incandescent burner, of a burner-head provided with a weight, a flat spiral spring which normally supports and carries the burner-head and retains its general transverse shape, and a tubular connection for supplying gas to said burner-head, substantially as described.

3. The combination in an incandescent burner, of a terminal spring-supported burner-head, and means supported independently of said spring for supplying a mixture of air and gas to said head, and a yieldingly-supported follower for said burner-head, substantially as described.

4. The combination in an incandescent burner, of a burner-head, a flat spiral spring for supporting and carrying said head, a Bunsen tube, and a yieldingly-supported follower for the burner-head, substantially as described.

5. The combination of a spring-supported burner-head and a yieldingly-supported follower, substantially as described.

6. The combination in an incandescent burner, of a rigid support, a flat spiral spring having its outer convolution attached to said support, a weighted burner-head supported and carried by the inner convolution of the spring, and a Bunsen tube extending into the base of said burner-head, substantially as described.

7. The combination in an incandescent burner, of a rigid support, a flat spiral spring, a weighted burner-head suitably supported by said spiral, a Bunsen tube extending into the base of said burner-head, and a yieldingly-supported follower for the burner-head, substantially as described.

8. The combination in an incandescent burner, of a rigid support provided with a groove, a flat spiral spring having its outer convolution seated in said groove, a burner-head carrying a mantle, a heavy body secured to the base of the burner-head and supported and carried by the inner convolution of the spring, and a connection for supplying gas to the burner-head, substantially as described.

9. The combination in an incandescent burner, of a weighted burner-head, a mantle carried thereby, a Bunsen tube extending into the base of the burner-head, a terminal spring supporting said burner-head and a yieldingly-supported follower for the burner-head, the arrangement being such that the burner-head is normally contained in axial relation to the spring, substantially as described.

10. The combination in an incandescent burner, of a mantle, a burner-head constructed to carry the mantle, a heavy body secured to the base

of said burner-head, a peripherally-contained flat spiral spring the inner convolution of which carries said heavy body and constitutes its sole support, and a Bunsen tube extending into the burner-head, substantially as described.

11. The combination in an incandescent burner, of a mantle, a burner-head constructed to carry the mantle, a heavy body secured to the base of said burner-head, a flat spiral spring the inner convolution of which carries said heavy body and constitutes its sole support, a Bunsen tube extending into the burner-head, and a spring-pressed follower for the burner-head, substantially as described.

12. The combination of a burner-head having a mantle, a weight constructed to carry the burner-head, a suitable casing having an annular groove or cut, a flat spiral spring whereof the outer convolution takes into said groove and whereof the inner convolution contains said weight, a connection for supplying a mixture of air and gas to the burner-head, and a spring-pressed follower, substantially as described.

13. The combination of a spring-supported burner-head, a spring-supported follower, and a loose lip-and-groove connection between the two, substantially as described.

700,158. TRUNK-STRAP. ORVILLE A. STUBBS, Norfolk, Va., assignor, by direct and mesne assignments, of two-thirds to Samuel E. Greene, Norfolk, Va. Filed July 20, 1891. Serial No. 70,008. (No model.)

Claim.—1. In combination, a lever member provided at one end with a recess, a strap fastened to the opposite end of the lever member, a catch member mounted upon the end portion of the strap fastened to the lever member and having a hook-shaped projection to engage fit within the above-mentioned recess of the lever member and positive interlocking means between the recessed end of the lever member and the hooked end of the catch member to secure the lever member when folded upon the catch member, substantially as specified.

2. In combination, a lever member having a recess at one end, and a notch and inner shoulder at the outer side of the said recess, a strap having an end portion fastened to the opposite end of the lever member, and a catch member mounted upon the end portion of the strap fastened to the lever member and having a hook-shaped projection to engage fit within the above-mentioned recess at the outer end of the lever member, said hook-shaped projection having a transverse slot for the passage of the strap, the latter passing through the notch at the outer side of the said recess, substantially as set forth.

3. The herein-described fastener comprising a lever member consisting of side bars, an intermediate and a terminal cross-bar, a plate connected to the upper or outer edges of the side bars and having a transverse slot opposite the intermediate cross-bar, the outer end of the lever member having a recess, an outer side of the recess having a notch and inner shoulder, a strap having an end portion folded around the terminal cross-bar and having its opposite end portion adjustably connected with the intermediate cross-bar, and a catch member consisting of a plate having a transverse slot at one end and a hook-shaped projection at its opposite end, and formed at its outer side with a transverse slot and at its inner side with a straight shoulder having an opening to receive the hook-shaped end of the lever member, substantially as set forth.

700,159. HORSESHOE. CHRISTIAN STRONG, Trenton, N. J. Filed Mar. 4, 1898. Serial No. 56,000. (No model.)

Claim.—1. In a duplex horseshoe, the hoof-plate having a downward-extending rib or flange formed by a single continuous web extending entirely along the inner edge of said hoof-plate, along the heel ends, thence forwardly along the outer edges, thence inwardly to form shoulders or ribs, and thence forwardly, intermediate between the inner and outer edges of the flanks of said hoof-plate, substantially as set forth.

3. The hoof-plate having a downward-extending rib or flange formed by a single continuous web extending entirely along the inner edge of said hoof-plate, along the heel ends, thence forwardly along the outer edges, thence inwardly to form shoulders or offsets, and thence forwardly, immediately between the inner and outer edges of the flanks of said hoof-plate to terminal points which are in a line with that part of the said rib or flange which is located at the extreme toe end of the inner edge of the said hoof-plate, substantially as set forth.

4. The hoof-plate having the downward-extending rib or flange formed by a single continuous web extending entirely along the inner edge and heel ends of said hoof-plate, thence forwardly along the outer edges, thence inwardly to form shoulders or offsets, and thence forwardly, these parts of said rib or flange which are located at the heel ends, and which form the shoulders or offsets being thickened or reinforced, substantially as and for the purpose set forth.

5. The hoof-plate having the downward-extending rib or flange formed by a single continuous web extending entirely along the inner edge and heel ends of said hoof-plate, thence forwardly along the outer edges, thence inwardly to form shoulders or offsets, and thence forwardly to points on a line with that part of the said rib or flange which is located at the extreme toe end of the inner edge of said hoof-plate, the latter being also provided at its extreme toe end with a downward-extending leg, in combination with the wear-plate having heel-calls extending beyond the outer edges of its flanks, and a toe-call the ends of which extend beyond the flanks of said wear-plate, substantially as and for the purpose set forth.

700,160. DENTAL MALL. JAMES W. TRAYNOR, San Francisco, Cal. Filed Jan. 25, 1902. Serial No. 91,160. (No model.)

Claim.—1. A device of the class described consisting of a pair of collets, a tool-holder having a portion thereof movable through said collets, an armature slidably mounted on said holder and in said collets and electrical connection.

2. A device of the class described consisting of aligned collets, a tool-holder movable in said collets, an armature slidably mounted on said holder and yieldingly held in said collets, and electrical connections so that movement of the holder in opposite directions will alternately energize said collets.

3. A device of the class described consisting of a collet, a tool-holder, electrical contact devices operated by movement of said holder, and an armature slidable on said tool-holder and adapted to effect said holder for the purpose set forth.

4. A device of the class described consisting of collets, a tool-holder protruding from said collets, a pin passing through said holder, thimbles encircling said holder and on opposite sides of said pin, and springs adapted to bear on said thimbles and return said pin to a normal position, and an armature in said collets and electrically connected to effect said holder.

5. A device of the class described consisting of collets, a tool-holder, a rod on said holder, contact devices in the path of said rod, a spring-yoke adapted to removably engage said contact devices, and electrical connections between the several parts.

6. A device of the character described, consisting of collets, a tool-holder having a portion thereof movable through said collets, electrical contact devices to meet with said collets, a yielding element between said contact devices movable by the said tool-holder to alternately energize the collets, and an armature slidable on the tool-holder, and electrical connections.

7. In a device of the character described, the combination with a pair of collets, a tool-holder movable through said collets, pistons arranged apart upon the tool-holder, an armature slidable within the said collets and adapted to engage the said pistons, and electrical connections.

8. A device of the class described, consisting of aligned collets, a tool-holder, an armature operated by said collets and having a movement independent of the said tool-holder, electrical means for energizing

said collets and means whereby the movement of the said holder will cause the said collets to be energized alternately.

700,161. TELEPHONE RECEIVER FOR WIRELESS SIGNAL APPARATUS. THOMAS TOSCANI, Geneva, Switzerland, assignor to Paul Galt, Geneva, Switzerland. Filed May 24, 1902. Serial No. 17,702. (No model.)

Claim.—1. In a telephonic signal-receiving apparatus for Hertzian rays, the combination with the electromagnet employed therein, of an armature, a disk of insulating material connected to but insulated from said armature and having a recess therein, coating powder retained in said recess, electrical conductors in contact with said coating powder and binding-posts to which their ends are connected, an electric circuit with terminals connected to the electromagnet, a relay and an electric circuit in which the relay is embodied with terminals connected to the binding-posts, and an aerial line and a line to ground also connected to said binding-posts substantially as and for the purpose specified.

2. In a telephonic signal-receiving apparatus for Hertzian rays, the combination with the electromagnet employed therein, of a movable diaphragm comprising the armature of the electromagnet, a disk of insulating material provided with a centrally-placed recess and connected to and insulated from the said diaphragm, metallic coating powder placed within said recess and means for retaining the same therein, electrical conductors in contact with said coating powder, binding-posts to which the ends of said conductors are secured, an aerial wire connected to one binding-post and a ground connection to the other binding-post, a battery, a relay, and electrical connections comprising a circuit whose terminals are said binding-posts, a battery and a recorder in circuit with the electric magnet and which circuit is closed by said relay, substantially as and for the purpose set forth.

700,162. HYDRAULIC CRANE. EDGAR C. WILLY, Bedford, Va., assignor of two-thirds to Henry E. McWane, Lynchburg, Va., and George L. Carter, Bristol, Tenn. Filed Mar. 1, 1902. Serial No. 6,905. (No model.)

Claim.—1. In a motive-fluid crane, the combination with a jib having a trolley, of a series of motor mechanisms carried by the crane-mast, said motor mechanisms comprising means for respectively swinging the crane on its vertical axis, lifting the load, and operating the trolley, common means for distributing the motive-agent supply to all of the motors, and individual controlling means for each motor.

2. In a motive-fluid crane, the combination with a jib having a trolley, of a common distributing valve-casing, a series of motor mechanisms carried by the mast and each having its supply and exhaust connected with said valve-casing, a load-lifting mechanism operable by one of said

motors, and means for swinging the jib and for operating the trolley, connected individually with the other motors, substantially as set forth.

3. In a motive-fluid crane, the combination with a jib carrying a trolley, of a load-lifting mechanism, a crane-swinging mechanism carried by the mast, a trolley-operating mechanism also carried by the mast, a main valve constituting a single source of supply to the motors of said load-lifting mechanism, the crane-swinging mechanism, and the trolley-operating mechanism, and operable to control directly the motor of the load-lifting mechanism, and independently-operable valves between said main valve and the motors for the crane-swinging and trolley-operating mechanisms, substantially as described.

4. In a motive-fluid crane, the combination with a jib carrying a trolley, of a main controlling-valve having a distributing-chamber and a single exhaust-passage, a load-lifting mechanism carried by the mast and having a motor which has its supply and exhaust connections controlled by the main valve, a crane-swinging mechanism also carried by the mast and including a motor which is connected with the distributing-chamber and exhaust of the main valve, and a trolley-operating mechanism also carried by the mast and having a motor likewise connected with the distributing-chamber and the exhaust of the main valve, the crane-swinging motor and the trolley-operating motor being controllable by individually-operable valves, substantially as set forth.

5. In a motive-fluid crane, the combination with the jib and the rotatable mast, of a series of motor mechanisms carried by the mast and comprising means for respectively swinging the crane on its vertical axis, lifting the load, and operating the trolley, a common distributing valve-casing connected with the several motor mechanisms and also carried by the mast, individual controlling means for each motor, and a single motive-fluid induction-pipe operatively connected with the said valve-casing, the pipe and the valve-casing being capable of relative rotation to communicate themselves in the turning movement of the mast, substantially as set forth.

6. In a motive-fluid crane, the combination with the rotatable mast, of a series of motor mechanisms mounted on and carried by the mast and comprising means for respectively swinging the crane on its vertical axis, lifting the load, and operating the trolley, a field-supply for all of said mechanisms, including a single distributing-casing having a single exhaust-passage, a controlling-valve arranged within the distributing-casing, a single motive-fluid induction-pipe communicating with said casing, and an automatic relief-valve also arranged in the same casing with said controlling-valve and interposed between the induction-pipe and the single exhaust-passage, substantially as set forth.

7. In a motive-fluid crane, the combination with the rotatable mast, of a series of motor mechanisms carried by the rotatable mast, and comprising means for respectively swinging the crane on its vertical axis, lifting the load, and operating the trolley, a common field-supply for all of said mechanisms, including a single distributing-casing, an individual controlling-valve for each motor mechanism, and an automatic relief-valve common to all of the controlling-valves of the system and arranged within the said distributing-casing, substantially as set forth.

8. In a motive-fluid crane, the combination with the jib and the rotatable mast, of a series of motor mechanisms carried by the rotatable mast and comprising means for respectively swinging the crane on its vertical axis, lifting the load, and operating the trolley, a common field-supply for all of said mechanisms, including a single distributing-casing, an individual controlling-valve for each motor mechanism, and an automatic relief-valve common to all of the controlling-valves, substantially as set forth.

9. In a motive-fluid crane, the combination with the rotatable mast, of a series of motor mechanisms carried by the mast and comprising means for respectively lifting the load, swinging the crane on its vertical axis, and operating the trolley, a single distributing valve-casing, a valve mounted in said casing for controlling the load-lifting mechanism, a relief-valve also arranged in said casing between the induction and exhaust ports, and separate valve connections between said distributing valve-casing and the motor mechanisms respectively for swinging the crane and operating the trolley, substantially as set forth.

10. In a motive-fluid crane, the combination with the horizontal stationary base, of an axially-rotatable crane-mast surmounting the base, a single upright crane-swinging motor mounted on and carried by the mast above the horizontal plane of the base, said crane-swinging motor having tackle connections respectively with the mast and with said stationary base, substantially as set forth.

11. In a motive-fluid crane, the combination with the stationary base, of an axially-rotatable mast surmounting the base, a single upright crane-swinging motor carried by the mast at a point above the stationary base, said motor comprising a double-acting cylinder, and a piston having tackle connections at opposite ends respectively with the mast and the stationary base, other mechanisms for respectively lifting the load and operating the trolley, and a common casing for distributing the motive-agent supply to the controlling valve-casings of all of the motors, substantially as set forth.

12. In a motive-fluid crane, the combination with the stationary base, and an axially-rotatable crane-mast surmounting the base, of a single upright crane-swinging motor mounted and supported directly on the mast at a point above the stationary base, the said motor comprising a cylinder, a piston having its rod extending through both ends of the cylinder, and tackle mechanism operatively connected with both ends of the piston-rod and having cables fastened respectively to the mast and to the stationary base, and means for controlling the admission and exhaust of the motive fluid to and from the cylinder, substantially as set forth.

13. In a motive-fluid crane, the combination with a stationary base, and a rotatable mast mounted thereon, of a single crane-swinging motor mounted on and supported by the rotatable mast, and separate cables respectively connected with opposite ends of the motor piston-rod, and also connected with the base.

14. In a motive-fluid crane, the combination with the stationary base, and an axially-rotatable mast arranged thereover, of a pair of spaced tiller-cherries bearing a fixed relation to each other and offset from one side of the mast at the lower end thereof, said cherries being arranged in close relation to each other and having the lower portions of their peripheries overhanging the periphery of the base and located in close proximal relation thereto, and a single crane-swinging motor supported directly upon and carried by the rotatable mast and having a pair of separate haulage-cables connected with the opposite ends of the motor piston-rod passing over the separate tiller-cherries, secured fast at their terminals to the stationary base, and extending respectively in opposite directions around the periphery of the latter, substantially as set forth.

15. In a motive-fluid crane, the combination with the stationary base, and an axially-rotatable mast arranged thereover, of a pair of adjacent, reversely-inclined tiller-cherries on the rotatable mast bearing a fixed relation to each other and offset from one side of the mast at the lower end thereof, said cherries being held in proximal relation to and having the lower portions of their peripheries overhanging and adapted to traverse the periphery of the said stationary base, and a single crane-swinging motor also carried by the mast and having a pair of separate haulage-cables connected with opposite ends of the piston-rod thereof and respectively passing around the separate tiller-cherries, and extending in opposite directions about the stationary base and attached directly to the latter, substantially as set forth.

16. In a motive-fluid crane, the combination of a stationary horizontal base having a peripheral groove, an axially-rotatable mast extending upward from the center of the base, a pair of adjacent reversely-inclined tiller-cherries carried by the rotatable mast and bearing a fixed relation to each other and offset from one side of the mast, at the lower end of the latter, said pair of cherries being in proximal relation to and having the lower portions of their peripheries overhanging the grooved periphery of the stationary base, and a single crane-swinging motor carried by the mast above the pair of cherries, and including separate and independent haulage-cables connected with opposite ends of the motor piston-

red, said separate cables being respectively attached to the mast and to the stationary beam, and also respectively passing around the idler-sheaves, so as to extend in opposite directions about the beam, substantially as set forth.

17. In a motive-fluid crane, the combination with the mast, the jib, and the trolley on the jib, of a plurality of motor mechanisms carried by the rotatable mast comprising means for respectively swiveling the crane on its vertical axis, lifting the load, and operating the trolley, the trolley-operating motor mechanism, having a double-acting piston, tackle connections between opposite ends of the piston-rod and the trolley, a motive-fluid-distributing device common to the several mechanisms, a four-way valve, and connections between said four-way valve and the motor-cylinders of the trolley-operating motor mechanism, substantially as set forth.

18. In a motive-fluid crane, the combination with the mast and jib, and a trolley on the jib, of a main controlling-valve having a distributing-chamber and a single exhaust, an induction-pipe operatively related to said main controlling-valve, an exhaust-pipe leading through the mast from the main controlling-valve, a lead-lifting mechanism carried by the mast and having its motor connected with said valve, a crane-swiveling motor carried by the mast and a trolley-controlling motor carried by the mast, and independent controlling-valves communicating with the distributing-chamber and exhaust of the main controlling-valve, and said valves also having operative connections with the crane-swiveling motor and the trolley-controlling motor, respectively, substantially as set forth.

19. In a motive-fluid crane, the combination with a rotatable mast, a jib carried thereby and a trolley movable on the jib, of a series of motors mounted on and carried by the mast, said motors comprising means for respectively swiveling the crane on its vertical axis, lifting the load, and operating the trolley, means for supplying motive power to all of the motors, and individual controlling means for each motor.

20. In a motive-fluid crane, the combination with the mast, and the jib having a trolley, three motors mounted on and carried by the mast, said motors each including essentially a rigidly-mounted cylinder, a piston, a valve and cable connections, one of the motors serving to swing the crane on its vertical axis, another acting to lift the load, and the third for operating the trolley, means for distributing a motive agent to the cylinders of each of the motors, and individual controlling means for each motor.

21. In a motive-fluid crane, the combination with a mast, and a jib and trolley carried thereby, of a series of motors comprising cylinders and pistons disposed vertically alongside the mast and supported thereon, said motors comprising means for respectively swiveling the crane on its vertical axis, lifting the load, and operating the trolley, and means for distributing a motive agent to each of the motor-cylinders, and controlling means for each motor.

22. In a motive-fluid crane, the combination with a rotatable mast, a jib carried thereby, and a trolley arranged to traverse the jib, of a double-acting motor comprising a cylinder mounted on the mast, a piston-rod, separate cables connected with opposite ends of the piston-rod and each having one end connected to a fixed part of the crane, and its opposite end connected with the trolley, and other motors also mounted on the mast, respectively for turning the mast and lifting the load.

700,168. WASTE-OIL-FILTERING APPARATUS. JOHN W. EVANS, Los Angeles, Cal., assignor of one-half to George A. Burwell, Jr., Denver, Colo. Filed Aug. 15, 1901. Serial No. 73,142. (No model.)

Claim.—1. In an oil-filter, the combination with an outer casing, provided with a flange surrounding the same on the inside, a suitable dis-

tance above its bottom, of a cushion supported by said flange, a receptacle resting on said cushion and comprising a bottom having a central opening, and an outer strainer portion, a stand-pipe whose lower extremity is open, said stand-pipe engaging said bottom and surrounding the central opening therein, a quantity of filtering material placed inside the receptacle, a strainer surrounding the stand-pipe and supported on the top of the receptacle, and a receptacle fitted into the upper part of the casing and communicating with the stand-pipe, the arrangement being such that a chamber for the filtered oil is left in the casing between the upper and lower receptacles.

2. The combination with an outer casing, surrounded by a flange on the inside, the flange being located a suitable distance above the bottom of the casing, of a cushion supported by said flange, a receptacle resting on said cushion and containing filtering material, a portion of the bottom of the receptacle consisting of a strainer, a strainer covering the top of the receptacle, a stand-pipe passed through the filter-receptacle said pipe being open at the bottom and communicating with the space below said receptacle, an enlargement attached to the top of the stand-pipe and fitted into the upper part of the casing, a strainer covering the top of the stand-pipe, filtering material located in the stand-pipe enlargement above the top of the stand-pipe, and a pipe communicating with the chamber in the bottom of the casing for the introduction of steam for the purpose of forcing out the filtered oil, the arrangement being such that there is a chamber for the filtered oil between the enlargement at the top of the stand-pipe and the filter surrounding its lower portion.

3. In an oil-filter, the combination with a casing, of a stand-pipe located therein, a funnel fitted into the casing and connected with the top of the stand-pipe, a filter surrounding the lower part of the stand-pipe and located a suitable distance above the bottom of the casing a plate located below the lower extremity of the stand-pipe, and suspended from the filter, a chamber for the filtered oil being left between the filter and the funnel, the arrangement being such that the oil poured into the funnel, passes downward through the stand-pipe and up through the filter in said chamber.

4. In an oil-filter, the combination with an outer casing of a cushion extending around the inside of the casing and supported thereon a suitable distance above its bottom, a filter resting on said cushion, a stand-pipe passed through the filter and communicating with the chamber below the latter, and a funnel fitted into the casing and communicating with the top of the stand-pipe, a chamber for the filtered oil being left around the stand-pipe between the funnel and the filter, the arrangement being such that the oil poured into the funnel passes through the stand-pipe into the chamber below the filter, and is forced through the filter into the chamber above, by the column of liquid in the stand-pipe, substantially as described.

5. In an oil-filter, the combination with a casing, a stand-pipe located therein and provided at the top with a funnel-shaped enlargement fitted into the casing, a filter surrounding the lower part of the stand-pipe, a chamber for the pure oil being left between the filter and the funnel, a plate attached to the filter below the lower extremity of the stand-pipe and a steam-pipe passed through the stand-pipe and terminating a short distance above the said plate whereby the steam is deflected outwardly as it enters the chamber below the filter.

REISSUES.

11,984. FINE-ROLLER. CHARLES W. H. MOON, Boston, Mass., assignor to The S. A. Webb Machine Company, Boston, Mass., a Corporation of Massachusetts. Filed Apr. 16, 1902. Serial No. 149,044. Original No. 696,207, dated Mar. 26, 1902.

Claim.—1. In a planing-machine, a plurality of upper feed-rolls, an adjustable carrier for supporting said feed-rolls on the frame of the machine, said feed-rolls being independently movable in said adjustable carrier, a single power-belt finally mounted on the frame of the machine and in engagement with said supporting means for adjusting the latter up and down while itself remaining vertically stationary, a weight and pressure-transmitting mechanism permitting said rolls to yield independently, including a connection from said weight to each of the upper feed-rolls, and means co-operating therewith, enabling the weight to give uniform tension or pressure to all of said rolls in all positions.

2. In a planing-machine, a pair of upper feed-rolls, an adjustable carrier (thereof), a weight located beneath the operating parts of the machine, and pressure-transmitting mechanism, including a chain, an equalizer, a chain-pulley fixed on said carrier, a chain-pulley movable relatively to said carrier, all co-operating with the chain, the equalizer and movable pulley yielding when a roll moves independently of the carrier.

3. In a planing-machine, a plurality of feed-rolls each movable up and down, a weight, connections between said weight and said several

rolls, including pressure-transmitting device for certain of said rolls, comprising means bearing down on the rolls, a pulley carried by said bearing-down means, and a chain passing over said pulley and connected with the weight for transmitting the pressure of the latter through said pulley and bearing-down means to the rolls.

4. In a planing-machine, a feed-roll, a movable carrier therefor, in which said feed-roll is movable up and down, a weight, two pressure-transmitting pulleys, one above the other, the upper pulley being movable independently of the lower pulley, a weight, and a chain connected to the weight and passing up over the upper pulley and over the lower pulley and up vertically to a fixed point of the frame of the machine to the weight.

5. In a planing-machine, a feed-roll, a movable carrier therefor in which said feed-roll is movable up and down, two pressure-transmitting pulleys, one above the other, the upper pulley being movable independently of the lower pulley, a weight, and a chain connected to the weight and passing up over the upper pulley and over the lower pulley and up vertically to a fixed point of the frame of the machine.

6. In a planing-machine, a feed-roll, a middle in which said feed-roll is journaled, vertical guide-frames in which said middle moves up and down, a pressure-transmitting device pivoted in said middle and provided with means for transmitting equal pressure to the opposite ends of said roll, the said roll being free to move up and down in said middle, a weight and a chain connection between said weight and said pivot device for transmitting the effect of said weight to said roll.

7. In a planing-machine, two feed-rolls placed end to end and mounted to move up and down, pivoted covers extending over said feed-rolls, a bar above said covers, a connection from said bar to the opposite ends of said rolls for the transmission of pressure from the bar to the rolls, connections between said covers and said bar, pulleys carried by said covers, a weight, and connections therefrom to said pulleys.

8. In a planing-machine, two feed-rolls placed end to end and mounted to move up and down, pivoted covers extending over said feed-rolls, contiguous journal-bases for supporting the adjacent journal ends of said two rolls, said bases extending above the rolls and said covers resting on said bases, a bar above said covers, a connection from said bar to the opposite ends of the rolls, connections between said covers and said bar, pulleys carried by said covers, a weight, and connections therefrom to said pulleys.

9. In a planing-machine, a feed-roll, a roll rigidly connected therewith and depending therefrom, a rigid bracket normally containing said roll and roll, a leg carried by said roll, a lever and weight pivoted intermediate its length to said leg and having its fulcrum at its end opposite

the weight, and an adjustable stop for regulating the downward movement of said leg.

10. In a planing-machine, a feed-roll vertically movable by the passage of timber, a weight connected thereto by a flexible connection, means for vertically adjusting said feed-roll, mechanism co-operating with said vertical adjusting means and said movable roll for changing the relative position of said roll and connection as the roll moves up and down independently of said adjustment, and including means maintaining uniform tension of said weight on said roll at all positions assumed by the latter.

11. In a planing-machine, a feed-roll vertically movable, a weight connected thereto by a flexible connection, pressure-transmitting pulleys relatively movable, said flexible connection passing over one of said pulleys and under the other, and means co-operating therewith enabling said weight to give uniform tension or pressure to said roll at all positions of its movement.

11,985. METAL DOOR-MAT. JOHN W. HANCOCK, Des Moines, Iowa, assignor to Hafferty Brothers, Marshalltown, Iowa. Filed Jan. 22, 1902. Serial No. 91,899. Original No. 697,573, dated Sept. 11, 1900.

Claim.—1. In a metal door-mat, the combination of the pivot-rod, the short pieces of flat metal bent laterally at their central portions and having their straight end portions perforated and pivotally mounted on the pivot-rod, the end portions of adjacent pieces overlapping each other across the pivot-rod and the outermost flange of the laterally-bent central portions of the short flat pieces being formed relatively long and arranged for mutual contact frictionally.

2. A flexible door-mat consisting of the pivot-rod, the short pieces of flat metal bent laterally at their central portions and having their end portions perforated and extended on a common plane and pivotally mounted on the pivot-rod, the end portions of adjacent pieces overlapping each other across the pivot-rod, the outermost flange of the laterally-bent central portions of the short flat pieces being formed relatively long and arranged for mutual contact frictionally, and end pieces pivoted on the outermost rods having the central portions conforming in contour to the pieces forming the body of the mat and the end portions bent on parallel planes, substantially as shown and described.

11,986. FURNACE-HYDRO-LAMP. EDWARD P. KENN, Alexandria, Va., assignor to the Kuhn Furnace-Hydro Lamp Manufacturing Company, a Corporation of Virginia. Filed Apr. 14, 1902. Serial No. 100,310. Original No. 698,199, dated Jan. 15, 1902.

Claim.—1. The combination in a furnace-hydro-lamp of a water-pen, a frusto-conical burner-pen of less diameter than the water-pen, so arranged therein as to leave an annular water-space between it and the water-pen, means for supporting the burner-pen within the water-pen as to leave a water-space between its bottom and the bottom of the water-pen in communication with the annular water-space, a body portion carrying a catalytic diaphragm and having its lower portion of a diameter greater than that of the burner-pen and extending down into the annular water-space, whereby the water contained in the water-pen is heated both by direct contact and by radiation from the catalytic diaphragm; substantially as described.

2. The combination in a furnace-hydro-lamp of a water-pen, a burner-pen of less diameter than the water-pen and so arranged therein as to leave an annular water-space between it and the water-pen, means for supporting the burner-pen as to leave a water-space between its bottom

and the bottom of the water-pan in communication with the annular water-space, a body portion carrying a catalytic diaphragm and having its lower portion extending down into the annular water-space, whereby the water contained in the water-pan is heated both by direct contact with the body portion and by radiation from the catalytic diaphragm; substantially as described.

3. In a formicohydro-lamp of the character described, the combination with the oxidizing-chamber and the burner arranged substantially as shown; of a platinum central diaphragm held within the oxidizing-chamber, a second platinum diaphragm disposed between the first diaphragm and the burner, said second diaphragm being of a less diameter than the first diaphragm, whereby to deflect the heat-rays from the first diaphragm, all being arranged substantially as shown and for the purposes described.

4. In a lamp of the character described, the combination with the burner having a burner-pan; of a casing having an oxidizing-chamber, a platinum diaphragm held in the said chamber, said casing extending up from the burner and adapted to normally rest with its lower edge surrounding the burner-pan, means for supporting the said casing to permit its being moved in a vertical plane to bring its entire lower edge in a plane above the burner-pan, whereby to permit of the insertion of a muffle-plate over the burner-pan, connecting device for joining the said casing detachably with the base, said connecting device including a pivotal joint to permit the said casing being swung laterally in a horizontal plane when the lower edge of the said casing is elevated in a plane above the burner-pan; substantially as shown and for the purposes described.

5. The combination in a lamp of the character described, with the burner-pan, and the oxidizing-chamber arranged above the pan; of an upper perforated platinum diaphragm extending entirely across the oxidizing-chamber and a lower platinum diaphragm of less diameter than the upper diaphragm, and means for supporting the lower diaphragm over the burner-pan, as specified.

6. The combination with the base, the burner-pan 2, the oxidizing-chamber, said chamber being open at the top and having a series of air-inlets at a point above the burner, of a platinum perforated diaphragm 3, held within the oxidizing-chamber at a point above the air-inlets and the perforated platinum diaphragm 7, held over the burner and at a point between the aforesaid air-inlets and the burner, as specified.

11,987. LOGGING-TRUCK. JOHN LUNNEY, Laurel, Miss, assignor to the Landry Wagon Company, Laurel, Miss. Filed Jan. 10, 1902. Serial No. 60,332. Original No. 664,214, dated Sept. 18, 1900.

Claim.—1. In a logging truck or cart, the combination, with an axle, wheel thereon and a pole or tongue extending forwardly from said axle, of a bolster secured to the axle, provided with a concave upper face, a pivoted cross-bar carried by the pole or tongue, a latch for the said cross-bar, and tongue connected with the said cross-bar, for the purpose specified.

2. In a logging truck or cart, the combination, with an axle, wheel loosely mounted on the axle, and a pole or tongue forwardly projected from the axle, of a bolster secured on the said axle, a cross-bar pivoted from one end on the pole or tongue, a latch for the opposite end of the cross-bar, a keeper carried by the said cross-bar, tongue, and a pliable and adjustable connection between the said keeper and said tongue, for the purpose specified.

3. A logging-truck, having a tongue, in combination with a cross-bar pivoted by one end to the tongue, means for locking said cross-bar in position transverse of the tongue, a chain-securing device on said cross-bar, a chain, and tongue adapted to engage a log, substantially as described.

4. A logging-truck, having a tongue, in combination with a cross-bar pivoted by one end to the tongue, means for locking said cross-bar in a position transverse of the tongue, a slotted plate extending upwardly from said cross-bar and having its upper ends curved forwardly, the slot in said plate being adapted to snugly embrace a chain-link placed laterally thereon, a chain adapted to fit in said slot, and tongue secured to said chain and adapted to lie on the truck-bolter when in use, substantially as described.

5. A logging-truck having an A-shaped tongue, and draft-attaching means at the forward end thereof, in combination with a cross-bar pivoted by one end to one side of the tongue, releasable jacking means for the other end of the cross-bar and adapted to hold the cross-bar transversely of the tongue, chain-securing means upon the cross-bar, a chain, and tongue secured thereto and adapted to secure a log, substantially as described.

6. The combination with a logging-truck having a wheeled axle and a horizontally-extended pole or tongue attached thereto, of a horizontally-extended bar mounted at one end on the pole or tongue near one side thereof, a log-gripping device adapted to engage the log, a connection between the gripping device and the bar, and a latch engaging the free end of the bar to hold the same and operate near the side of the pole or tongue opposite the pivot of the bar.

7. The logging-truck wherein are combined an axle, low wheel thereon, a tongue extending forward from said axle, a bolster on the axle having its top extending approximately to the height of the wheel, and a grappling device secured to the tongue forward of the axle and carried over the top of the bolster and supported thereon, substantially as specified.

11,988. VALVE AND ALARM. FRANK GRAY, Chicago, Ill. Filed July 12, 1900. Serial No. 730,714. Original No. 626,161, dated May 18, 1900.

Claim.—1. In a pressure-stilling system, the combination with the main valve between the supply-pipe and the distributing-pipes, of alarm mechanism normally subject to and retained out of effective action by static pressure beyond said valve on the distributing side thereof, agencies for positively closing or locking said valve, and means whereby the effective manipulation of said agencies causes a variation in the pressure on said distributing side and a consequent sounding of the alarm.

2. In a pressure-stilling system, the combination with the main valve between the source of supply and the distributing-pipes, of alarm mechanism normally subject to and retained out of effective action by static pressure beyond said valve on the distributing side thereof, agencies for locking said valve in its rest, and means whereby the ineffectual movement of said agencies is immediately attended with an initial variation of pressure on said distributing side and consequent sounding of the alarm.

3. In a pressure-stilling system, the combination with a combined check-valve and shut-off valve, and a drain or release valve, manually-operated means for closing and locking the check-valve into a cut-off or shut-off valve, and connections which invariably open the drain or release valve concurrently with the closing and locking aforesaid, from the same point of manual operation, of an alarm or alarm operated by the reduction of pressure caused by the opening of the drain or release valve, whereby an alarm is invariably sounded whenever the pressure in the system is cut off.

4. In a pressure-stilling system, the combination with a check-valve and a drain or release valve, and manually-operated means for positively closing and locking the check-valve into a shut-off valve, of connections unitarily controlled from the same point of manual operation, which cause the initial opening of the release-valve to accompany the ineffectual movement of said means for locking the check-valve, and an alarm or alarm immediately and positively set in action by the regulation of pressure attendant upon such initial opening.

5. In a self-contained piece of valve apparatus, a drain or release valve, a spindle or shaft upon which the drain-valve is mounted and by which it is operated, a check-valve, and means carried by the shaft or spindle which close and lock the check-valve, whereby it becomes a shut-off or cut-off valve.

6. In a self-contained piece of valve apparatus, a spring-pressed drain or release valve, a spindle or shaft to which said valve is affixed with capacity to slide lengthwise thereof, a check-valve located internally of said shaft, and a cam upon the shaft and acting against the check-valve, whereby the turning of the shaft closes and locks the check-valve and opens the drain-valve.

7. In a self-contained piece of valve apparatus, a spring-pressed drain or release valve, a spindle or shaft upon which the drain-valve is mounted and by which it is operated, and means carried by the shaft, having a very slight lead over the drain-valve, for positively closing and locking the check-valve, whereby the initial opening of the cam is immediately attendant upon the ineffectual closing of the other.

11,989. AUTOMATIC CAN-HEADING MACHINE. ANDREW W. LAYMOND, Alameda, Cal., assignor to the American Can Company, New York, N. Y., a Corporation of New Jersey. Filed Feb. 10, 1902. Serial No. 60,001. Original No. 660,600, dated Jan. 7, 1902.

Claim.—1. An automatic can-heading machine comprising conveyors by which the heads and bodies are separately introduced into the machine, and the heads placed upon the bodies, said can-head conveyor having notches or steps on its surface adapted to engage the rear edge of the head as the latter is advanced, means for advancing the heads on their conveyor and means for securing the heads and bodies.

2. In a can-heading machine, a can-head conveyor having a retainer bottom adapted to engage the rear edge of the head, in combination with means for advancing the heads along the conveyor.

3. An automatic can-heading machine, including superposed conveyors one of said conveyors having a retainer bottom adapted to engage the rear edge of the head as the latter is advanced, means for advancing the heads on their conveyor, a revolving table upon which the heads and bodies are delivered, means for centering the heads upon the bodies, and means whereby the heads and bodies are secured and the cans delivered from the machine, the operation throughout being entirely self-regulating.

4. In a can-heading machine, the combination of conveyors for the heads and bodies, a can-head conveyor including a retainer bottom to engage the rear edge of the head, means for advancing the heads, a table upon which the heads and bodies are received, guides and supports which receive and center the heads upon the bodies, and means by which the bodies and heads are united and secured.

5. In a can-heading machine, the combination of a can-body conveyor, a can-head conveyor having a retainer surface to engage the can-head, means for advancing the heads on their conveyor, a revolving table upon which the heads and bodies are delivered, and the heads centered upon the bodies, a pressure-plate by which the parts are united, and means for moving the cans of the heads and bodies.

6. In an automatic can-heading machine, an endless conveyor upon which the can-bodies are supported, a superposed conveyor carrying the can-heads, the latter conveyor having a retainer bottom adapted to engage the rear edge of the heads as the latter are advanced, a reciprocating means by which this advance is made, and means whereby the heads and bodies are united and secured.

7. In an automatic can-heading machine, a conveyor supporting the can-bodies, a superposed reciprocating conveyor supporting the can-heads, means by which the can-bodies may be automatically discharged from the conveyor in case the cans are fed thereon too rapidly, a revolving table upon which the bodies are received, guides or spindles upon this table and revolving therewith and whereby the bodies are held thereon and the can-heads are received and centered upon the bodies, and means by which the flanges of the heads and bodies are united in a tight joint.

8. In an automatic can-heading machine, a revolving table, means for delivering can-bodies thereon, guides or spindles against which the bodies are received and held in place, one of these spindles provided with projecting pins by which the entering can-heads are centered over and placed upon their respective bodies, means by which the head is pressed down upon the body, and means whereby cans unsupplied with heads are ejected from the spindles.

9. In an automatic can-heading machine, a revolving table, guides or spindles thereupon and revolving therewith, means by which can-bodies are delivered into the spindles, a reciprocating carrier delivering the can-heads upon the bodies, pins upon the spindles by which the centering of the heads and bodies is effected, a pawl upon the reciprocating rod of the can-head carrier whereby cans unsupplied with heads are ejected from the spindles.

10. In an automatic can-heading machine, a revolving table, conveyors by which can-bodies and can-heads are delivered simultaneously upon this table, spindles by which these bodies are held, projections upon certain of the spindles, whereby the heads are guided and centered upon the bodies, a fixed segmental plate under which the bodies and heads are passed, and the heads forced tightly upon the bodies, an annular groove in the bottom of the plate allowing the spindles to revolve freely therebeneath.

11. In an automatic can-heading machine, the combination with a revolving table upon which the can-bodies and can-heads are received, and the heads placed in position upon the bodies, of a revolving support upon which the cans are delivered from the said table, means for revolving these cans independently of the revolution of the said support, and means whereby the cans are carried, and a tension member connected to the arms and by which the rollers are held against the can and adjustment made for the cans in the revolution of the table, said rollers each performing only a part of the operation of centering.

12. In an automatic can-heading machine, a revolving support or drum, brackets upon the upper and lower portions of the drum and projecting horizontally beyond the circumference thereof, an upper and lower set of checks, connections with the drum-shaft whereby the upper checks are revolved, and means, including a centrally-located roller having one end connected with the lower check-spindle, and a cam-surface in the path of the other end of said roller whereby the lower checks may be made to approach the upper checks and hold securely same interposed between the lower checks and their respective upper checks.

13. In an automatic can-heading machine, a revolving support or drum, an upper and lower set of checks carried thereon outside of, and concentric with, the circumference of said drum, connections whereby the upper checks are made to revolve independently of the revolution of the drum, each of the lower checks provided with a lever, each centrally-located and having one end connected with the lower check-spindle by which a lower check may be lifted and made to hold a can firmly between it and its respective upper check, and means including a cam in the path of the other end of the lever for operating this lever.

14. In an automatic can-heading machine, a revolving support or drum, an upper and lower set of revolvable checks carried thereon, each of the lower checks connected with one end of a lever, which latter is centrally-located, and having its other end adapted to engage a cam whereby a lower check is lifted toward its respective upper check and a cam firmly held between the two checks, a bar on the spindle of each lower check and to which the upper end of the lever is connected, and a cushion between the bar and a fixed part adapted to relieve the jar when the bar is suddenly lifted.

15. In an automatic can-heading machine, a revolving support or drum, brackets upon the drum carrying an upper and lower set of checks, means by which the upper checks are revolved, the spindles of each of the lower checks made slidable in its journal, a collar upon each spindle, a bar upon the spindle and below the collar, a spring interposed between the collar and the bar, one end of a lever slidable in this bar, the lever centrally-located and having a roller upon its lower end which is adapted to engage, during the revolution of the drum, a cam and raise the lower check and bind the can held thereon against a respective upper check, causing the checks and can to revolve together.

16. The combination in an automatic can-heading machine with a revolving support or drum, of a means by which can-bodies with their can-heads in position may be delivered upon a lower set of checks and beneath an upper set of checks upon this drum, means by which the upper checks are revolved independently of the revolution of the drum, a centrally-located lever in connection with each of the lower checks, one end of which attaches to the spindle of the check and the other is provided with a roller adapted to engage an annular cam-plate upon the frame by the revolution of the drum, whereby the lower check is raised and the can brought in contact with the upper check, securely held and rapidly revolved, causing engaging and crimping the flanges of the can, means

by which the lower check is again dropped and the can delivered from the machine.

17. The can-heading machine, consisting in combination, of a horizontal endless conveyor upon which the can-bodies, having exterior and flanges, are carried, guides upon this conveyor, an automatic discharge gate at the inner end of the conveyor, a second conveyor superposed above the first, consisting of a reciprocating rod, flanges upon this rod adapted to engage the can-bodies, a rotatable bottom to this carrier by which the edges of the head are stopped and prevented from backward movement by the reciprocation of the rod and flanges, a guide by which the head is prevented from transverse or lateral displacement, a revolving table upon which the can-bodies are delivered, spiders thereon to hold and guide these bodies, the upper spider provided with pins which arrest the can-bodies, center them above the can-bodies and allow them to drop in place upon the latter; a fixed segmental pressure-plate under which the bodies and heads in position, now known as cans, are passed by the revolution of the table and its spider, and the heads firmly pressed down upon the bodies so as to bring their extending flanges in close contact; a pawl upon the end of the reciprocating rod extending over the table by which bodies unsupported with heads are ejected from the spider; guides by which the cans are led onto and centered upon lower checks upon a revolving drum, said checks turnable in journals upon their bracket-supports, each of these checks provided with a corresponding upper check, which latter is revolved independently of the revolution of the drum; a means by which the lower checks may be lifted and the cans held thereon forced against the upper checks and revolved, adjustable cammers engaging the flanges of the bodies and heads, certain of these cammers adapted to roll the cans, and certain of them adapted to flatten and finish the cans, and means for releasing the cans from the checks and delivering them from the machine.

18. The combination with a continuously-revolving can-carrier drum or support having a plurality or series of individually-rotating can-checks thereon, of a plurality or series of swinging arms or levers on the frame, at different positions around said continuously-revolving drum, and provided with a plurality or series of double-convex rollers for forming concave portions or steps of a double cam on the cans as they pass, each camming-roller engaging the can while the drum turns through a segment or one of its revolutions, substantially as specified.

19. The combination with a continuously-moving can-carrier, a plurality of rotating can-checks thereon, a plurality of double-convex rollers, and a plurality of swinging arms mounted on the stationary frame of the machine and adapted to move with the camming-rollers thereon out of the way of the cans as they pass, and hold the cans in engagement therewith, and double-convex rollers mounted on said swinging arms, substantially as specified.

20. The combination with a series of continuously-traveling rotating can-checks, of a series of double-convex rollers arranged in the path of the cans and engaging the cans successively as they pass, substantially as specified.

21. The combination with a continuously-moving can-carrier provided with a series of rotating can-checks of a plurality of double-convex rollers each performing a part of the camming operation and successively engaging the rotating cans as they pass, substantially as specified.

22. The combination with a continuously-driven can-carrier having a plurality of rotating can-checks thereon of a plurality of movable double-convex rollers each in turn engaging each can as it passes, substantially as specified.

23. The combination with a continuously-traveling series of rotating can-checks with a series of camming-rollers arranged in the path of the cans for successive operation on each can as it passes in its traveling check, substantially as specified.

11,990. CAR-BRAKE. HENRY J. SMALL, Birmingham, Cal., assignor to the Westinghouse Air Brake Company, Pittsburgh, Pa. Filed Mar. 21, 1908. Serial No. 88,948. Original No. 510,203, dated Dec. 8, 1900.

Claim.—1. The combination, in a railroad-car brake, of a brake-cylinder, a brake-cylinder lever for actuating truck-brake levers at both ends of a car by fluid-pressure in said cylinder, a hand-brake lever, and connections from the hand-brake lever to the brake-cylinder lever and to hand-brake devices at each end of the car, said connections adapting the brake-cylinder lever to be operated by the hand-brake lever from either end of the car, and in the same direction as by the fluid-pressure in the brake-cylinder, substantially as set forth.

2. The combination, in a railroad-car brake, of a hand-brake lever, hand-brake devices at both ends of a car connected to said hand-brake lever, a fluid-pressure cylinder fitted with a piston and rod, a lever adapted to be actuated in the same direction, independently by either of the end hand-brake devices or by the piston-rod of the fluid-pressure cylinder, and connections coupling said lever to the hand-brake lever, substantially as set forth.

3. The combination, in a railroad-car brake, of a system of truck-brake levers for actuating connected brake-choses, a fluid-pressure brake apparatus coupled thereto, an independent hand-brake apparatus operated from either end of the car, and a flexible connection coupling the hand-brake apparatus with a member of the fluid-pressure brake apparatus having the capacity of independent movement relatively to the actuating piston-rod thereof, substantially as set forth.

4. The combination, in a railroad-car brake, of a system of truck-brake levers for actuating connected brake-choses, a fluid-pressure cylinder having a piston and rod, an intermediate connection coupled positively to one of said truck-brake levers, and coupled to the piston-rod with the capacity of independent movement, two hand-brake connecting-rods adapted to be actuated by manual power from either end of the car, and a flexible connection by which the hand-brake connecting-rods are coupled to the intermediate connection of the piston-rod and truck-brake lever, substantially as set forth.

5. The combination, in a railroad-car brake, of two systems of truck-brake levers, adapted to actuate connected brake-choses on trucks at opposite ends of a car, a fluid-pressure cylinder having a piston and rod, an intermediate connection coupled positively to a lever of each of said systems, and coupled to the piston-rod with the capacity of independent movement, two hand-brake connecting-rods coupled one to the other and adapted to be actuated by manual power applied at either end of the car, and a flexible connection by which the hand-brake connecting-rods are coupled to the intermediate connection of the piston-rod and truck-brake lever, substantially as set forth.

6. The combination, in a railroad-car brake, of a brake-chose, a brake-lever connected thereto, a fluid-pressure cylinder fitted with a piston and rod, a brake-cylinder lever coupled to said rod with the capacity of independent movement, and coupled positively to the lever of the brake-chose, a hand-brake connecting-rod, an independent hand-brake lever coupled thereto, and a flexible connection coupling said independent hand-brake lever to the brake-cylinder lever, substantially as set forth.

7. The combination, in a railroad-car brake, of a brake-chose, a brake-lever connected thereto, a fluid-pressure cylinder fitted with a piston and rod, a slotted cross-head fixed to said rod, a brake-cylinder lever coupled to the lever of the brake-chose, and traversing on the piston-rod cross-head, a hand-brake connecting-rod, an independent hand-brake lever coupled thereto, and a flexible connection coupling said independent hand-brake lever to the brake-cylinder lever, substantially as set forth.

8. The combination, in a railroad-car brake, of two systems of truck-brake levers, adapted to actuate connected brake-choses on trucks at opposite ends of a car, a fluid-pressure cylinder fitted with a piston and rod, a brake-cylinder lever having a fixed fulcrum, and coupled to a brake-lever of one of the trucks, a brake-cylinder lever having a fulcrum which is movable on an extension of the piston-rod, and coupled to a brake-lever of the other truck, a rod coupling said brake-cylinder levers one to the other, two hand-brake connecting-rods coupled one to the other and adapted to be actuated by manual power applied at either end of the car,

and a flexible connection by which the hand-brake connecting-rods are coupled to one of the brake-cylinder levers, substantially as set forth.

9. The combination, in a railroad-car brake, of two systems of truck-brake levers, adapted to actuate connected brake-choses on trucks at opposite ends of a car, a fluid-pressure cylinder fitted with a piston and rod, an intermediate connection coupled positively to a lever of each of said systems and coupled to the piston-rod with the capacity of independent movement, two hand-brake connecting-rods each adapted to be actuated by manual power applied at one end of the car, an independent hand-brake lever coupled to one of said hand-brake connecting-rods, an auxiliary brake-lever coupled to the other hand-brake connecting-rod and to the independent hand-brake lever, and a flexible connection coupling the independent hand-brake lever to the intermediate connection of the piston-rod and truck-brake lever, substantially as set forth.

DESIGNS.

85,904. HANDLE FOR SPOONS OR FORKS. FREDERICK H. PIERCE, Brooklyn, N. Y., assignor to George W. Shubler and Company, New York, N. Y., a firm. Filed Apr. 4, 1908. Serial No. 181,008. Term of patent 24 years.

Claim.—The design for the handle of a spoon or fork, substantially as shown and described.

85,905. HARPIN BRIDGE. EVELYN BRYSON, Chicago, Ill. Filed Mar. 14, 1908. Serial No. 88,448. Term of patent 24 years.

Claim.—The design for a harpin holder as herein shown and described.

85,906. STAMP OR ENVELOPE MOUNTING. MARCUS A. MCGRATH, Indianapolis, Ind. Filed Apr. 17, 1908. Serial No. 180,088. Term of patent 14 years.

Claim.—The design for a stamp and envelope mounter as herein shown and described.

85,907. CUT-GLASS RECTANGLE. CARL V. REICHENBERGER, Hartford, Conn., assignor to the C. F. Maurice Company, Hartford, Conn., a Corporation of Connecticut. Filed Apr. 18, 1908. Serial No. 180,092. Term of patent 24 years.

Claim.—The design for a cut-glass rectangle as herein shown and described.

85,908. LAMP-FIXTURE. THOMAS MOORE JAMISON, Memphis, Tenn. Filed Mar. 1, 1902. Serial No. 94,344. Term of patent 24 years.

Claim.—The design for a lamp-fixture, substantially as shown and described.

85,909. VEHICLE-BODY. JOHN H. MAGALIAN, Somerville, Mass. Filed Feb. 12, 1902. Serial No. 94,345. Term of patent 7 years.

Claim.—The design for vehicle-body herein described and shown.

85,910. VEHICLE-BODY. JOHN H. MAGALIAN, Somerville, Mass. Filed Dec. 19, 1901. Serial No. 94,319. Term of patent 7 years.

Claim.—The design for vehicle-body as herein shown and described.

85,911. VEHICLE-BODY. JOHN H. MAGALIAN, Somerville, Mass. Filed Feb. 12, 1902. Serial No. 94,346. Term of patent 7 years.

Claim.—The design for vehicle-body herein shown and described.

85,912. FURNITURE. CHARLES EDWARD EMMER, Louisville, Ky. Filed Apr. 7, 1902. Serial No. 101,540. Term of patent 7 years.

85,912.

Claim.—The design for a dresser as herein shown and described.

85,913. DRAPERY-TRIMMING. GEORGE S. BROWN, Philadelphia, Pa. Assignor to Brown & Brown Company, a Corporation of Pennsylvania. Filed Apr. 15, 1902. Serial No. 100,000. Term of patent 14 years.

Claim.—The design for a drapery-trimming substantially as shown and described.

85,914. FRIDGE. WILLIAM T. BROWN, Philadelphia, Pa. Filed Apr. 21, 1902. Serial No. 104,500. Term of patent 7 years.

Claim.—The design for a fridge, substantially as described and as shown in the accompanying drawing.

85,915. RUG. EDWARD E. BROWN, East Orange, N. J., assignor to John E. Brown and Edward Brown, partners trading as John Brown & Son, Philadelphia, Pa. Filed Apr. 22, 1902. Serial No. 104,501. Term of patent 24 years.

Claim.—The design for a rug, substantially as shown and described.

TRADE-MARKS

REGISTERED MAY 13, 1902

88,224. RIBBONS. LAM & WICKHAM, New York, N. Y. Filed Mar. 20, 1902.

CONQUEROR

The word "CONQUEROR." Used since January 11, 1900.

88,225. COTTON TEXTILES, INCLUDING SHIRTINGS AND SHIRTINGS. HOWARD L. STUBBS, New York, N. Y. Filed Mar. 17, 1902.

RAMOPA

The word "RAMOPA." Used since March 5, 1903.

88,226. COTTON FABRICS. WARD, HANNEY & Co., London, Eng. Filed Mar. 1, 1902.

The representation of an archer carrying a bow with the string drawn back and the arrow in position to be discharged, the archer being mounted upon a galloping horse with a flowing mane and tail and the archer carrying a shaft of arrows. Used since April 16, 1901.

88,227. COTTON FABRICS. WARD, HANNEY & Co., London, Eng. Filed Mar. 1, 1902.

The representation of a man mounted on a fish, the fish being in the act of flying or leaping out of a body of water. Used since April, 1900.

88,228. COTTON FABRICS. WARD, HANNEY & Co., London, Eng. Filed Mar. 1, 1902.

The representation of a group of boys each standing in an upright position and carrying branches of foliage bearing leaves. Used since April 16, 1901.

MAY 13, 1902.

U. S. PATENT OFFICE.

2511

88,229. COTTON FABRICS. WARD, HANNEY & Co., London, Eng. Filed Mar. 4, 1902.

The representation of a lion or Chinese dragon, the latter having a wide-spread tail and represented as standing in an erect posture upon the upper surface of a platform and leaning upon a shield. Used since April, 1900.

88,230. COTTON FABRICS. WARD, HANNEY & Co., London, Eng. Filed Mar. 4, 1902.

The representation of a Chinese Emperor of olden times, in which the person of the Emperor is shown as an erect figure dressed in mailed armor, having in his right hand a tufted spear and wearing a sword and belt of antique style. He also carries a shaft of arrows, has a flowing cape, and a flowing beard, and the head is surmounted with a crested or helmet provided with plumes. Used since April 16, 1901.

88,231. COTTON FABRICS. WARD, HANNEY & Co., London, Eng. Filed Mar. 20, 1902.

The representation of a lion, eagle, and globe, the eagle being perched above the earth and grasping the globe in its claws and beneath it the lion is in an erect position, the whole with a background of natural scenery. Used since September 22, 1900.

88,232. COTTON FABRICS. WARD, HANNEY & Co., London, Eng. Filed Mar. 20, 1902.

The representation of the announcement of the winning of a prize in the winner thereof in which the latter is represented as a Chinaman seated at a table, having his arms spread at the receipt of the news, which is represented as displayed upon a placard in the hands of a messenger, also dressed in Chinese fashion and who is represented in a kneeling posture. Used since April 16, 1901.

88,233. CERTAIN WARMED FABRICS. GENERAL WILSON, New York, N. Y. Filed Apr. 2, 1902.

The representation of the stern portion of a sailing vessel and that of a helmsman having hold of the steering-wheel and looking calmly into the compass in front of him, a portion of the boom and sail of the vessel appearing overhead of the helmsman and the words "OLD RELIABLE" appearing in the lower portion of the picture. Used since December 1, 1901.

88,984. CERTAIN MARKED FABRIC. GEORGE WILSON, New York, N. Y. Filed Apr. 3, 1902.

The representation of a sailing ship on the water, and the word "HOMEWARD" appears printed on the water below the said representation, both the representation and word being included in a border. Used since January 1, 1902.

88,985. CERTAIN MARKED FABRIC. GEORGE WILSON, New York, N. Y. Filed Apr. 4, 1902.

The representation of a man in the business dress of a pioneer, with a powder-horn at one side, a gun in one hand, and in the act of stepping forward, and below this representation appears the word "ONWARD," all being included in a double-line border. Used since March 1, 1902.

88,986. CERTAIN MARKED FABRIC. GEORGE WILSON, New York, N. Y. Filed Apr. 4, 1902.

A picture entitled the "The Man Behind the Gun," the picture disclosing a portion of between-decks of a man-of-war, a gun, a gunner behind the gun in standing position, a helper at one side of the gun in kneeling position, a projectile-carriage in the foreground, and two men-of-war appearing at a distance through a port-hole. Used since December 1, 1901.

88,987. CORSETS. GEORGE WILSON, New Haven, Conn. Filed Feb. 4, 1902.

C/B

The letters and diagonal line "C/B." Used since January 1, 1877.

88,988. LEATHER GOODS AND SHOES. BROWN & WOODBURY & Co., Boston, Mass. Filed Mar. 20, 1902.

Triumph

The word "TRIUMPH." Used since March 1, 1902.

88,989. BOOKS AND PAPER. HARRY HUNT & SONS Co., Grand Rapids, Mich. Filed Oct. 20, 1901.

88,989.

The representation of a desert scene with a caravan in the foreground and pyramids, started vegetation, and the sun in the background. Used since April 12, 1901.

88,940. STEEL PENS. H. HYMAN & SONS, Birmingham, England. Filed Apr. 1, 1902.

SILVER SERIES.

The words "SILVER SERIES." Used since March 1, 1902.

88,941. HYGIENIC AND FOUNTAIN PENS. J. GRADY & Co., New York, N. Y. Filed Apr. 4, 1902.

JUCO

The word "JUCO." Used since March 25, 1902.

88,942. GLASS TILES. THE SOLAR TILE CO., Cleveland, Ohio. Filed Mar. 24, 1902.

The word "SOLAR" and the representation of a winged sun associated with a rectangle covered with parallel lines and also having a small circle at its center. Used since September 1, 1900.

88,943. NUDE-BOILER. HENRY HUNT & SONS Co., Grand Rapids, Mich. Filed Apr. 20, 1901.

Princess

The word "PRINCESS." Used since March 26, 1902.

88,944. NUDE-BOILER. HENRY HUNT & SONS Co., Grand Rapids, Mich. Filed Apr. 20, 1901.

Queen

The word "QUEEN." Used since March 18, 1902.

88,945. REMEDIES FOR CURS OF RHEUMATISM, NEURALGIA, AND BRACHIAL. N. C. KANE & SONS, Brooklyn, N. Y. Filed Mar. 14, 1902.

A rectangular figure having three in the foreground the representation of a sailor leaning against the upright stock of an anchor partly buried in the sand, the background showing the sea. Used since February 1, 1902.

88,946. REMEDIES FOR CERTAIN MARKED DISEASES. THE HENRY HUNT & SONS Co., Grand Rapids, Mich. Filed Mar. 14, 1902.

The letters "E. T. B." and a border including the same. Used since March 10, 1902.

88,947. CERTAIN MARKED TOILET PREPARATIONS. THE VIOLETTA HUNT Co., New York, N. Y. Filed Mar. 12, 1902.

The representation of two cornucopias flanking each other and overflowing with powder, producing a bed of powder upon which a crown appears to rest. Used since January 15, 1902.

88,248. MEDICATED BATHING COMPOUND. JEAN HOLMES.
Havran, Ohio. Filed Nov. 2, 1901.

The representation of a Cuban landscape with a village in the background, with the sun above the village, a piece of open country in front of the village, four palm trees arranged in a group on the right of the picture, a rock in the foreground at the left, and a group of persons in an expectant attitude in the middle ground. Used since October 2, 1900.

88,249. OIL FOR MEDICINAL PURPOSES. BUCKING CEMENTAL COMPANY, Boston, Mass. Filed Feb. 1, 1902.

ESKE-MO

The hyphenated word "Es-Ke-Mo" and the picture of a standing figure represented as holding a cup in one hand, from which he is dropping liquid from a bottle held in the other hand, the hyphenated word "Es-K" appearing on the bottle. Used since November 1, 1901.

88,250. CHOCOLATE CONFECTIONS. H. D. FORD AND CO., INCORPORATED, Boston, Mass. Filed July 15, 1901.

QUALITY

The word "QUALITY." Used since September, 1897.

88,251. MINERAL WATER. BARNARD'S BOTTLES, New York, N. Y. Filed Apr. 6, 1902.

DEEPWOOD

The word "DEEPWOOD." Used since March 27, 1902.

88,252. WHISKIES AND CHAMPS. HENRI & BERTH, Albuquerque, N. Mex. Filed Mar. 22, 1902.

Alvarado Club

The words "ALVARADO CLUB." Used since November, 1901.

88,253. CHAIRS, CHAMBERS, AND CHAIRS. H. B. BELL, Berlin, Switzerland. Filed Jan. 2, 1902.

The representation of a female figure in a fancy costume, the left arm outstretched, holding a flower in the hand, and the right hand clasped behind the head. Used since January 1, 1902.

88,254. BUTTER, CHEESE, AND EGGS. HENRI & BERTH, Berlin, Switzerland. Filed Mar. 11, 1902.

The representation of a four-leaf clover on a leaf of a tree appearing on a contrasting background bounded by intersecting circles, the background appearing within a rectangular dotted field containing spaced representations of a four-leaf clover. Used since January 1, 1902.

88,255. FLOUR. BROWN & ALLEN, York, Pa. Filed Apr. 2, 1902.

HALF & HALF

The two words "HALF & HALF." Used since 1901.

88,256. FLOUR. S. & P. FLOUR CO., Boston, Mass. Filed Apr. 7, 1902.

The word "APOLLO," together with the representation of a statue of the god Apollo and surrounding decorative circles. Used since May 25, 1901.

88,257. CERTAIN BAKED FOOD PRODUCTS. BUFFALO CEREAL COMPANY, Buffalo, N. Y. Filed Mar. 26, 1902.

WINNER

The word "WINNER." Used since March 1, 1902.

88,258. LEATHER PRESERVATIVE. JAMES JAMES PRESERVATIVE, Harrison, W. Va. Filed Jan. 15, 1902.

LEATHER LIFE

The words "LEATHER LIFE." Used since November 1, 1901.

88,259. CLEANING AND POLISHING SOLUTION. GRAMER & GRAMER, Buffalo, N. Y. Filed Apr. 7, 1902.

VARNUE

The word "VARNUE." Used since March 20, 1902.

88,260. SMALL. WILSON & SONS, New York, N. Y. Filed Apr. 12, 1902.

VIVOID

The word "VIVOID." Used since March 15, 1902.

88,261. SMALL. WILSON & SONS, New York, N. Y. Filed Apr. 12, 1902.

ULTROID

The word "ULTROID." Used since March 15, 1902.

88,969. SMALL. WHITING & BROWN, New York, N. Y. Filed Apr. 18, 1908.

RAVENOID

The word "RAVENOID." Used since March 15, 1908.

88,968. SMALL. WHITING & BROWN, New York, N. Y. Filed Apr. 18, 1908.

NICROID

The word "NICROID." Used since March 15, 1908.

88,964. SMALL. WHITING & BROWN, New York, N. Y. Filed Apr. 18, 1908.

CHROMOID

The word "CHROMOID." Used since March 15, 1908.

88,965. ASPHALT ROOFING. BARNES CLARKSON, Chicago, Ill. Filed Apr. 3, 1908.

VULCANITE

The word "VULCANITE." Used since March, 1908.

88,966. HYGIENIC COMPOSITION OR CEMENT. WARREN ENGINEERING COMPANY, Boston, Mass. Filed Apr. 7, 1908.

STONETIED

The word "STONETIED." Used since January 1, 1908.

88,967. HYGIENIC COMPOSITION OR CEMENT. WARREN ENGINEERING COMPANY, Boston, Mass. Filed Apr. 7, 1908.

WARRENE

The word "WARRENE." Used since January 1, 1908.

88,968. HYGIENIC COMPOSITION OR CEMENT. WARREN ENGINEERING COMPANY, Boston, Mass. Filed Apr. 7, 1908.

BITUROCK

The word "BITUROCK." Used since January 1, 1908.

88,969. HYGIENIC COMPOSITION OR CEMENT. WARREN ENGINEERING COMPANY, Boston, Mass. Filed Apr. 7, 1908.

BITUSTONE

The word "BITUSTONE." Used since January 1, 1908.

88,970. HYGIENIC COMPOSITION OR CEMENT. WARREN ENGINEERING COMPANY, Boston, Mass. Filed Apr. 7, 1908.

WARRO

LITHIC

The word "WARROLITHIC." Used since January 1, 1908.

88,971. HYGIENIC COMPOSITION OR CEMENT. WARREN ENGINEERING COMPANY, Boston, Mass. Filed Apr. 7, 1908.

WARREN

PHALT

The word "WARRENEPHALT." Used since January 1, 1908.

88,972. HYGIENIC COMPOSITION OR CEMENT. WARREN ENGINEERING COMPANY, Boston, Mass. Filed Apr. 7, 1908.

STONEPHALT

The word "STONEPHALT." Used since January 1, 1908.

88,978. HYGIENIC COMPOSITION OR CEMENT. WARREN ENGINEERING COMPANY, Boston, Mass. Filed Apr. 7, 1908.

ASPHALROCK

The word "ASPHALROCK." Used since January 1, 1908.

88,974. HYGIENIC COMPOSITION OR CEMENT. WARREN ENGINEERING COMPANY, Boston, Mass. Filed Apr. 7, 1908.

WARRENITE

The word "WARRENITE." Used since January 1, 1908.

88,975. HYGIENIC COMPOSITION OR CEMENT. WARREN ENGINEERING COMPANY, Boston, Mass. Filed Apr. 7, 1908.

ROCKPHALT

The word "ROCKPHALT." Used since January 1, 1908.

88,976. HYGIENIC COMPOSITION OR CEMENT. WARREN ENGINEERING COMPANY, Boston, Mass. Filed Apr. 7, 1908.

ROCKBOUND

The word "ROCKBOUND." Used since January 1, 1908.

88,977. HYGIENIC COMPOSITION OR CEMENT. WARREN ENGINEERING COMPANY, Boston, Mass. Filed Apr. 7, 1908.

BIG FOUR

The word "BIG FOUR." Used since January 1, 1908.

88,978. HYGIENIC COMPOSITION OR CEMENT. WARREN ENGINEERING COMPANY, Boston, Mass. Filed Apr. 7, 1908.

METALINE

The word "METALINE." Used since January 1, 1908.

88,979. HYGIENIC COMPOSITION OR CEMENT. WARREN ENGINEERING COMPANY, Boston, Mass. Filed Apr. 7, 1908.

BITUWARREN

The word "BITUWARREN." Used since January 1, 1908.

88,980. VARNISHES. REYNOLDS VARNISH & OIL CO., LONDON, Toronto, Canada. Filed Apr. 4, 1908.

ELASTILITE

The word "ELASTILITE." Used since July 20, 1908.

88,981. ANTI-INCORPORATING COMPOUND FOR STEAM-BOILERS. ADRIAN W. HANSEN, Philadelphia, Pa. Filed Mar. 15, 1902.

CHAMPION

The word "CHAMPION." Used since November, 1893.

88,982. CIGARETTES. HARRY GUNN, Chicago, Ill. Filed Apr. 24, 1902.

ABNER

The word "ABNER." Used since May 24, 1900.

88,988. BRILLIA. W. E. WILSON & Co. New York, N. Y. Filed Nov. 25, 1901.

The representation of an alligator in a pond. Used since February 5, 1901.

88,984. INSULATING TUBES OR TUBULAR COVERINGS FOR ELECTRIC WIRES. AMERICAN CABLE LACE CO., Chicago, Ill. Filed Feb. 20, 1902.

Spots of distinctive color produced by or applied to the external surface of an insulating tube or tubular covering for electric wires. Used since 1890.

LABELS

REGISTERED MAY 13, 1902.

DECISIONS

OF THE

COMMISSIONER OF PATENTS

AND OF

UNITED STATES COURTS IN PATENT CASES.

COMMISSIONER'S DECISIONS.

EX PARTE VERLEY.

Decided September 11, 1901.

1. ANTICIPATION—COMMISSIONER—REJECTION UPON TWO REFERENCES—OZONE APPARATUS.

A claim covering an ozonizer in combination with a particular apparatus for producing currents of high frequency held lacking in patentable novelty in view of two prior patents, one showing an ozonizer in combination with one form of high-frequency apparatus and the other showing the particular high-frequency apparatus claimed in combination with different translating devices.

2. SAME—DOUBLE USE.

Held that the substitution of one old form of high-frequency apparatus for another in the production of ozone involves mere double use and not invention.

APPEAL from Examiners-in-Chief.

ELECTRICAL MACHINES.

Application of Albert Verley filed October 2, 1897, No. 653,809.

Messrs. Pollak & Mauro for the appellant.

ALLEN, Commissioner:

This is an appeal from the decision of the Examiners-in-Chief affirming the rejection by the Primary Examiner of the following claim:

In an electrical machine for producing ozone, the combination with the secondary circuit of a transformer, of a condenser connected in and adapted to be charged by said circuit, and an effervescence apparatus into which said condenser discharges its electricity, one plate of the condenser being metallically continuous with one plate of the effervescence apparatus, and the other plate of the condenser having an interruption or air-space in its connection with the other plate of the effervescence apparatus.

The references are patents to Tesla, June 23, 1891, No. 454,633; Tesla, November 3, 1891, No. 463,410; Tesla, September 28, 1896, No. 568,177.

The fundamental idea of this invention seems to be to use high-frequency currents for the production of ozone. The appellant makes use of a particular apparatus to produce the currents of high frequency and applies them to what is known as an "ozonizer."

It is old to apply currents of high frequency to an ozonizer to produce ozone, as disclosed in the patent to Tesla, No. 568,177, cited, and it is old to produce currents of high frequency by the same means as that described by the appellant, as shown by the other patents to Tesla, Nos. 454,633 and 463,410, cited, and therefore the only question presented for decision is: Was invention required to substitute the old form of high frequency apparatus for the apparatus used for the same purpose in

Tesla's Patent No. 568,177 in connection with an ozonizer?

In his Patent No. 568,177 Tesla recognized the fact that high-frequency currents were necessary for use with an ozonizer and described a particular apparatus which he intended to use to generate such currents. It would seem that after this disclosure any one skilled in the art would understand that any means disclosed in the art for producing the currents of the requisite character could be substituted for the particular means shown. That Tesla's previous devices produced currents of that character is apparent from the patents themselves and is furthermore indicated by Tesla in his Patent No. 568,177, wherein he states that the apparatus used by him is of the same general character as his previously-patented devices for producing high-frequency currents. After referring to his previous devices he says:

In my present improvement I have utilized appliances of this general character.

If there were any doubt whether the adaptability of Tesla's earlier devices to the production of ozone would be apparent to one skilled in the art, it would be dissipated by the reference in the ozone patent itself to those devices as being of the same general character as the one then used for the production of ozone. This reference would suggest the idea if it were not apparent from an inspection of the appliances disclosed.

In his Patent No. 454,633 Tesla happens to show his apparatus for generating currents of high frequency used for operating lamps; but it is obviously adapted for use with other translating devices requiring currents of high frequency, and that Tesla understood this is indicated by statements in the patent. To merely substitute it for the particular means shown in Patent No. 568,177 for the same purpose—viz., to produce currents of high frequency—would clearly not involve inventive thought.

The appellant argues that his device is the first one to practically and successfully produce ozone and that Tesla's devices are theoretical merely and not practical. This Office has no means to verify this contention. Whether or not Tesla has actually made devices which successfully produce ozone he has described to the public how it may be done, and his description would convey the same idea to those skilled in the art as to what means should

be employed as would the appellant's description. If one skilled in the art could produce a successful device from the appellant's description, it is believed that he could do so from the disclosure in Tesla's patents. The devices would be of the same construction if the apparatus for generating high-frequency currents of Patent No. 454,022 were used with the oscillator of Patent No. 538,177.

The decision of the Examiners-in-Chief is affirmed.

EX PARTE EICKEMEYER.

Decided April 26, 1902.

1. ASSIGNMENT—SUBJECT TO LICENSE—ISSUING PATENT TO ASSIGNEE.

Where an instrument is recorded in this Office transferring the invention "subject to a license," Held that the patent will not be issued to the assignee.

2. SAME—SAME—EFFECT OF LICENSE.

Where an instrument transfers an invention "subject to" a previous instrument referred to as a license, Held that without an inspection of the first instrument it cannot be determined whether or not the second conveys the entire title.

ON petition.

ELECTRIC LOCOMOTIVE.

Application of Rudolf Eickemeyer filed August 10, 1892, No. 442,722.

Mr. A. G. Davis for the applicant.

ALLEN, Commissioner:

This is a petition that the patent to be granted on the above-entitled application may be issued to the General Electric Company as assignee in view of certain assignments of record in the Patent Office.

It appears from the records of this Office that the application in question has been transferred by direct and mesne assignments to the General Electric Company. By these assignments all right, title, and interest in the invention, application, and Letters Patent is transferred to the latter company—

subject to a license as to hoisting apparatus granted by instrument dated June 14, 1893, made by the Eickemeyer and Osterheld Manufacturing Company, Rudolf Eickemeyer, Henry Osterheld, and Rudolf Eickemeyer, Jr., the Eickemeyer Dynamo Machine Company and Otis Brothers and Company, parties of the first part, and Duncan Smith as trustee, party of the second part.

Under the law (sec. 4893, R. S.) the Commissioner of Patents has discretionary authority to grant and issue patents to the assignee of the inventor or discoverer, provided that the assignment be first entered in the Patent Office. In the carrying out of this provision of the law Rule 26 of the Rules of Practice provides that—

In case of an assignment of the whole interest in the invention, or of the whole interest in the patent to be granted the patent will, upon request of the applicant, be assigned to the assignee.

It is clear from the provision of the statute and of the rule quoted above that the Commissioner may issue the patent to the assignee of the whole interest instead of to the inventor. It is equally clear that if the assignment be of an interest less than the whole there is no authority by which the patent may be granted to the assignee exclusively.

The question presented in the case now under consideration is: Do the assignments of record con-

vey the whole interest in the application and the patent to be granted therein to the General Electric Company?

In answering this question the difficulty is found in the words "subject to a license, etc.," as recited above. If this alleged license is of such a nature that neither the monopoly nor an undivided part thereof is conveyed, it does not affect the legal title to the invention or the patent to be granted therefor. (*Russell v. Kern*, 58 Fed. Rep., 382; *Waterman v. McKenzie*, 138 U. S., 302.) The mere fact, however, that the instrument is described in the various assignments as a license is not of itself sufficient to establish the real character of the rights covered by said instrument. This can be determined only by an inspection of the instrument in order that these rights may be ascertained. Should it appear upon such inspection that the rights are of such a nature as to convey the monopoly or any part thereof, it is clear that the General Electric Company cannot have the whole interest in the present application nor in the Letters Patent to be granted thereon.

The reference to this license in the assignments which are of record in this Office raises a doubt as to the exact interest which these assignments convey. They may or may not convey the whole interest. Under these circumstances this Office should not undertake to determine the nature of the rights conveyed by the assignments, but in the exercise of the discretionary power conferred by law should issue the patent to the applicant.

The petition is denied.

EX PARTE WORDEN.

Decided April 15, 1902.

DIVISION—TWO SPECIES—LIMITATION BEFORE ACTION ON MERITS.

When an application contains a generic claim and claims for two distinct species, a requirement that the claims be limited to a single species is equivalent to a requirement for division under Rule 41. This limitation should be made prior to any action on the merits.

ON petition.

SUGAR-CASHEWTS.

Application of Will J. Worden filed January 2, 1902, No. 80,181.

Mr. James J. Shesky for the applicant.

ALLEN, Commissioner:

This is a petition that the Examiner—be advised that applicant is entitled to an action on the merits of claim 1 before deciding which of two sets of specific claims he will prosecute in this application, and that the Examiner be directed to give such action.

It appears that the application contains a generic claim and claims for two distinct species of the invention covered by this generic claim. The Examiner has required a limitation of the claims to a single species before action on the merits.

This requirement is equivalent to a requirement for division under Rule 41. Hence the question whether or not action on the merits should be given prior to a compliance with the requirement for limitation of the claims is to be determined by Rule 41.

This rule provides that when the independence

[Vol. 99.

No. 7.]

of the inventions is clear limitation will be made before any action on the merits; otherwise it may be made at any time before final action thereon, in the discretion of the Examiner.

It is not denied that the claims of the present application cover two distinct species, which cannot both be retained in the same case. It is clear, therefore, that the action of the Examiner requiring limitation before action on the merits was correct.

The petition is denied.

EX PARTE HOUGHTON.

Decided April 15, 1902.

1. LABELS—PRINTED MATTER—NOT REGISTERABLE.

A label which contains nothing more than an arrangement of printed matter naming and describing a medicine, together with directions for its use and the name and residence of the manufacturer, is not an artistic production and is not registrable.

2. SAME—ARBITRARY WORD—NOT ARBITRARY.

A label containing a new arbitrary word may be an intellectual production; but such a word does not render the label registrable.

3. SAME—ABSENCE OF ARTISTIC MERIT.

In the absence of artistic merit there is no provision for the registration of a label under the statute relating to copyrights, under which statute such registration is granted.

ON appeal.

LABEL FOR MEDICINAL PREPARATION.

Application of Alfred S. Houghton filed March 15, 1902, No. 2,616.

Mr. Houghton pro se.

ALLEN, Commissioner:

This is an appeal from the action of the Examiner refusing to register a label entitled "Dr. Houghton's Rheumalgine," to be used upon a medicinal preparation.

Registration has been refused because the label involves in its production nothing beyond the expected skill of the type-setter.

An inspection of the label shows that the objection is well taken. It contains nothing more than an arrangement of printed matter naming and describing the medicine, together with directions for its use and the name and address of the manufacturer. It is well settled that such a label is not registrable. (*Ex parte Baldwin*, 98 O. G., 1706; *ex parte Mahn*, 99 O. G., 1310.)

Applicant contends that the label is an intellectual production because of the word "Rheumalgine," which, he states, is of his own coinage, to convey the idea of a remedy opposed to rheumatic pain. However this may be, it is clear that this label is not an artistic production, and for this reason it is not registrable. As was said in *ex parte Mahn*, supra:

The law was designed to give protection to the maker of a new creation possessing artistic merit.

In the absence of artistic merit there is no provision for the registration of a label under the statute relating to copyrights, under which statute such registration is granted.

The action of the Examiner was correct and is affirmed.

[Vol. 99. No. 7.]

EX PARTE NICHOLS AND SHEPARD COMPANY.

Decided April 26, 1902.

TRADE-MARK—THE WORDS "RED RIVER SPECIAL" HELD NOT REGISTRABLE.

The words "Red River Special" held not to be registrable as a trade-mark for agricultural machinery on the ground that the words "Red River" are geographical and the word "Special" is indicative of grade or style, and therefore the mark is not as an entirety indicative of origin or ownership. (*Brown v. Trade-Marks*, sec. 340, 347; *ex parte Buffalo Pitts Co.*, 99 O. G., 309.)

ON appeal.

TRADE-MARK FOR AGRICULTURAL MACHINERY.

Application filed November 26, 1901, No. 64,561.

Mr. Rowford M. Smith for the applicant.

ALLEN, Commissioner:

This is an appeal from the refusal of the Examiner to register the words "Red River Special" as a trade-mark for agricultural machinery consisting of threshing-machines, clover-hullers, and grain-separators.

The Examiner refused to register the mark "Red River Special" on the ground that "the words 'Red River' are geographical and the word 'Special' is indicative of grade or style and therefore the mark" is not as an entirety indicative of origin or ownership.

An affidavit has been filed by the president of the company to the effect that the goods are manufactured at Battlecreek, Mich., and that the words "Red River Special" are used in an arbitrary and fanciful sense, that threshing-machines manufactured by the company are not built in any place or locality by the name of Red River and are not built for the purpose of being sold in such a place or locality, and that there is no place or locality by the name of Red River in which any threshing-machines are built.

The test as to the registrability of a mark which has geographical significance is whether the arbitrary or fanciful meaning of the mark so overcomes its geographical meaning that the mark would ordinarily be accepted in its arbitrary or fanciful sense and not as designating locality. (*Ex parte Monogue-Pidgeon Iron Company*, 97 O. G., 3084; *ex parte Huensfeld*, 98 O. G., 1968.) In order, therefore, to warrant the refusal of registration, the geographical meaning of the mark must be predominant. In the case of the words "Red River" the geographical meaning is predominant.

These words signify a parish in the State of Louisiana, a county in the State of Texas, and an important river flowing into the Mississippi, forming certain State and Territorial boundary-lines in the southern portion of this country, and the words "Red River of the North" signify another well-known river running from southern Canada through a portion of the northern part of this country. The Red River Valley of the North through which this river flows signifies a section of country noted for its agricultural products.

The words "Red River" cannot be said to have any other than a geographical meaning. There is no fanciful suggestion attaching to these words to overthrow their geographical significance.

The word "Special" alone is clearly not registrable. This is conceded by the appellant. The words "Red River" and the word "Special" not being registrable when used alone are not registrable when combined. (*Brown on Trade-Marks*, secn. 344, 347; *ex parte Buffalo Pitts Co.*, 80 O. G., 2009.)

The decision of the Examiner is affirmed.

VANDEN BERGH AND COMPANY v. BELMONT DISTILLERY COMPANY.

Decided April 22, 1902.

1. TRADE-MARK INTERFERENCE—BURDEN OF PROOF—REGISTRATION UNDER THE ACT OF 1870.

Where in a trade-mark interference one of the applicants had in 1870 registered the mark under the Invalid Trade-Mark Act of 1870, *Held* that he is not entitled to the date of that registration in deciding upon whom the burden of proof shall be placed.

2. SAME—REGISTRATION AS EVIDENCE OF OWNERSHIP.

Under the present trade-mark law registration is *prima facie* evidence of ownership, and therefore the opposing party must show use in the United States before its date; but this does not apply to registration under the old law, which has been held *non est*.

3. SAME—SAME—PRESENT LAW AND OLD LAW COMPARED—USE NOT REQUIRED.

Registration under the act of 1870 has merely the effect of a printed publication and conveys no presumption of use in this country, since that act did not require use as a condition precedent to registration.

APPEAL ON MOTION.

TRADE-MARK FOR SPIRITUOUS LIQUORS.

Application of Vanden Bergh and Company filed February 20, 1901, No. 63,735. Trade-mark to Belmont Distillery Company registered April 23, 1899, No. 16,504.

Messrs. Brice & Knauth for Vanden Bergh and Company.

Messrs. H. B. Wilson & Co. and Mr. W. H. Singleton for Belmont Distillery Company.

ALLEN, Commissioner:

This is an appeal by Vanden Bergh and Company from a decision of the Primary Examiner denying their motion to shift the burden of proof in the above-entitled interference to the Belmont Distillery Company.

The records show that this interference was declared on December 4, 1901, and that the applicants, Vanden Bergh and Company, and the registrant, Belmont Distillery Company, were made, respectively, the junior and senior parties thereto under the well-settled practice of this Office because of their respective dates of filing.

This relation between the two parties makes it incumbent upon the junior parties to be the first to take testimony.

In view of the fact that the senior party is a registrant and of the further fact that section 7 of the Trade-Mark Act approved March 3, 1881, provides "that registration of a trade-mark shall be *prima facie* evidence of ownership" it is essential for the applicant in order to be entitled to an award of priority to establish, among other things, a date of

[Vol. 90.

use of the trade-mark in the United States prior to the date of the other party's registration.

In this interference, however, the applicants and appellants, Vanden Bergh and Company, call attention to the fact that they registered the same mark for the same class of goods on April 23, 1870, under the Trade-Mark Act of 1870. They argue that this registration is a part of the records of this Office and should be recognized and entitles them to an award of priority should the opposing party take no testimony. They therefore contend that this registration of 1870 entitles them to be recognized as the senior party to this interference. The registration of 1870 was declared unconstitutional by the Supreme Court of the United States. (*Trade-Mark Cases*, 100 U. S., 82.) This registration therefore amounts to nothing more than a publication and can have no more force and effect as against the common-law trade-mark rights of another party than any other publication. It cannot have the effect of a registration under the act of 1881, as provided in section 7 of said act. Furthermore, the registration of 1870 conveys no presumption of use in the United States. The law then in force did not require as a condition precedent to registration use in the United States, but was satisfied by a mere intention to so use. Moreover, the records show that the applicants have their domicile abroad and there is no allegation of use in the United States prior to the date of filing of the present application.

The decision of the Examiner refusing to shift the burden of proof is affirmed.

HOFFSTETTER v. KAHN.

Decided April 22, 1902.

INTERFERENCE—NOTICES—RULE 97 REQUIRES DISCLOSURE BY TITLE OF INVENTION.

The requirement of Rule 97 that the notices of interference should disclose "the invention claimed" means that the invention claimed should be disclosed by its title.

ON REFERENCE.

AS COOKING-STOVE.

Application of Charles H. Hoffstetter for gas or vapor burners. Application of Lazard Kahn for gas cooking-stoves.

Mr. H. T. Fisher and Messrs. Blackwood Bros. for Hoffstetter.

Mr. James W. See and Mr. F. B. Brock for Kahn.

ALLEN, Commissioner:

A disagreement having arisen between the Examiner of Interferences and the Primary Examiner as to the construction of Rule 97, this interference is referred for decision under the provisions of Rule 99.

In the notices of interference prepared by the Primary Examiner the title of the invention of the opposing parties has not been disclosed. The Examiner of Interferences is of the opinion that one of the provisions of Rule 97 is that the notices should disclose to the opposing parties the titles of the inventions claimed. For this reason he held

No. 7.]

the notices in this case to be defective and "transmitted his objections to the Primary Examiner." (Rule 98.) The Primary Examiner is of the opposite opinion and promptly notified the Examiner of Interferences of his decision not to amend the notices. (Rule 98.)

The question involved is not one which can in any way affect the proper determination of the question of priority of invention or the rights of either party to this proceeding and for this reason is not of great moment. It merely involves the construction of the phrase "the invention claimed" in Rule 97.

The rule requires that the notices of interference shall disclose, among other things, "the ordinals of the conflicting claims and the invention claimed; and the issue."

The Primary Examiner is of the opinion that the invention claimed is disclosed by means of the issue, and therefore the requirement that the notices shall disclose "the invention claimed; and the issue" is a mere repetition.

The Examiner of Interferences is of the opinion that the rule requires the invention claimed to be disclosed by its title in addition to the issue and the counts thereof. It is the general rule of the Office in designating an application for a patent to refer to it by the name of the inventor, the title of the invention, the serial number, and its date of filing. In a notice of interference it would be manifestly improper to designate the application involved by its serial number and its date of filing. In view of this fact it is necessary to refer to the same by the only other available means of identification—namely, the name of the inventor and the title of the invention claimed. The rule specifically provides for a disclosure of the name of the inventor. It also provides for a disclosure of the invention claimed as well as for a disclosure of the issue. The issue of course is in one sense a disclosure of the invention claimed, but in many cases it would be impossible to tell the nature of the invention from a mere reading of the issue.

Many claims begin with the expression:

Is a device of the class described, the combination, etc.

In considering such a claim the disclosure of the title would be of material assistance in determining the nature and scope of the invention claimed.

The Primary Examiner states that—

It was the practice years ago to include in the notice of interference to each party, the title of the invention of the opposing party. Some Examiners may still continue to do so, but most of the Examiners have long since ceased to do so, and the notices with a useless recital of the title of the opposing party's invention.

In reply the Examiner of Interferences states:

There has been no violation of what is believed to be the requirement of the rule in this respect, and if in certain cases notices have been sent out from the Interference Division in which this requirement has not been complied with, it has been through inadvertence or oversight.

The requirement of Rule 97 that "the invention claimed" be disclosed means that the invention claimed should be disclosed by its title.

The objection made by the Examiner of Interferences to the notices is well taken, and they should be amended in conformity with this decision.

[Vol. 90. No. 7.]

DECISIONS OF THE U. S. COURTS.

Court of Appeals of the District of Columbia.

IN RE SWINBURNE.

Decided April 1, 1902.

1. FOREIGN PATENT—SECTION 4887, REVISED STATUTES—BAR TO PATENT HERE.

Where an application is filed in this country on April 22, 1898, for an invention patented in England and it appears that the application and provisional specification were filed in the British Patent Office on May 1, 1897, the complete specification was filed February 28, 1898, and was accepted June 1, 1898, and the patent was sealed and delivered August 16, 1898, *Held* that the application here cannot be allowed in view of section 4887, Revised Statutes.

2. SAME—SAME—DATE OF BRITISH APPLICATION—PROVISIONAL SPECIFICATION.

The time of filing the application in the British Patent Office accompanied only by the provisional specification must be taken as the date of the application for the foreign patent within the meaning of section 4887, Revised Statutes. (*Ex parte Smith*, 55 O. G., 2031, cited with approval.)

3. SAME—SAME—ORIGINAL PAPER REQUESTING PATENT.

Independent of the form or function of either specification that may be filed in connection with it the instrument entitled the application throughout the British patent law remains the initiatory step in the proceeding to obtain a patent under that law and must therefore fix the date from which the limitation of section 4887, Revised Statutes, begins to run.

4. SAME—SAME—PROVISIONAL SPECIFICATION AND CAVEAT CONSIDERED.

Held that the original paper called the "application" is not a mere introduction to the provisional specification and that the provisional specification is not the equivalent of a caveat under the United States law.

Mr. Hermann C. Wollereck and Mr. F. C. Somes for the appellant.

Mr. John M. Cott for the Commissioner of Patents.

SHEPARD, J.:

The appellant appeals from a decision of the Commissioner of Patents denying his application for a patent for an improvement in the process of treating sulfid ores.

The appellant holds a British patent for the same invention issued as of May 1, 1897. His application was filed in the United States Patent Office April 22, 1898.

The sole ground of refusal is that the present application was filed more than seven months after the filing of the application for the British patent.

Section 4887 Revised Statutes which regulates the subject reads as follows:

No person otherwise entitled thereto shall be debarred from receiving a patent for his invention or discovery, nor shall any patent be declared invalid, by reason of its having been first patented or claimed to be patented by the inventor or his legal representatives or assigns in a foreign country, unless the application for said foreign patent was filed more than seven months prior to the filing of the application in this country, in which case no patent shall be granted in this country.

Section 5 Part II, of the British Patent Act contains five clauses regulating applications for patents.

Clause (3) provides:

An application must contain a declaration to the effect that the applicant is in possession of an invention whereof he claims to be the true and first inventor, and for which he desires to obtain a patent; and must be accompanied by either a provisional or complete specification.

Clause (3):

A provisional specification must describe the nature of the invention, and be accompanied by drawings, if required.

Clause (4):

A complete specification, whether left on application or subsequently, must particularly describe and ascertain the nature of the invention, and in what manner it is to be performed, and must be accompanied by drawings, if required.

Clause (5):

A specification, whether provisional or complete, must commence with the title, and in the case of a complete specification must end with a distinct statement of the invention claimed.

Every application so made is referred to an Examiner who shall report whether the invention has been fairly described, etc., and whether the title sufficiently indicates the subject-matter of the invention. (*Idem* sec. 6.)

If the Examiner reports that the nature of the invention is not fairly described, or the application, specification and drawings are not in proper form, or that the title does not sufficiently indicate the subject-matter of the invention, the Comptroller shall require amendments. (*Idem* sec. 7.)

If a complete specification is not left with the application, the applicant has nine months within which to file the same; and if not so filed the application shall be decreed to be abandoned. (*Idem* sec. 8.)

When the complete specification is left within the time, the Comptroller shall refer both the provisional and the complete specification to an examiner to ascertain whether the latter has been prepared in the prescribed manner—

and whether the invention particularly described in the complete specification is substantially the same as that which is described in the provisional specification. (*Idem* sec. 9.)

When the application has been approved—a patent shall be sealed as soon as may be and not after the expiration of fifteen months from the date of application, except, &c. . . . (*Idem* sec. 12.)

Clause (3):

Every patent shall be dated and sealed as of the day of the application: Provided that no proceedings shall be taken in respect of an infringement committed before the publication of the complete specification. . . . (*Idem* sec. 13.)

It appears from the record, that on May 1, 1897, the applicant filed his application in the British Patent Office in the required form accompanied by a provisional specification describing the nature of his invention as required.

On February 28, 1898, he lodged in the Patent Office a complete specification in conformity with the requirements thereof. June 1, 1898, the complete specification was accepted and on August 16, 1898, a patent was sealed and delivered, dated, however, as of May 1, 1897, when the original application and provisional specification had been filed.

The decisions of the Patent Office tribunals in this case adopt, without further discussion, the conclusion of Mr. Commissioner Duell, in another case decided December 20, 1896, and from which there was no appeal, to the effect that the time of filing the application in the British Patent Office, accompanied only by the provisional specification, must be taken as the date of the application for the foreign patent within the meaning of section 4867 Revised Statutes above quoted. (*Ex parte Smith*, S. C. C. D., 1898, 278; 35 O. G. 2091.)

That decision, in which the question was fully discussed, meets with our approval after a careful consideration of its grounds in the light of the able argument that has been presented on behalf of the

appellant, and leaves little, if anything, to be said in support of its conclusion.

We think that no other meaning can reasonably be deduced from the language of the British statute than that the application therein provided for, which may be accompanied by only a provisional specification, at the option of the applicant, is the application for the patent which may thereafter be issued upon a complete specification. As was said by Mr. Commissioner Duell in the decision before cited:

The complete specification is merely an amplification of the provisional specification. The provisional specification differs from the complete specification in that the former must describe the nature of the invention and the latter must particularly describe and ascertain the nature of the invention and in what manner it is to be performed.

We find nothing in opposition to this view in the recent decision in the Chancery Division of the High Court of Justice in England, to which our attention has been invited. (*Pneumatic Tyre Co. Company, Ltd. v. East London Rubber Company*, Vol. XIV, No. 5; *Reports of Patents, Design and Trade Mark Cases*, p. 77.)

On the contrary it seems to be directly upheld by the following expression in the opinion in that case:

Undoubtedly, in a provisional specification you must find the nature of the invention, though it need not be described otherwise than roughly to show as it is fairly described. But the provisional specification need not describe the manner in which the invention is to be carried into effect.

The first step of the inventor in the proceeding to secure a patent is called, and referred to as the application, throughout the British statute regulating proceedings in the Patent Office. This application is nowhere confounded with the provisional specification that must accompany it, or the complete specification that may be filed within nine months thereafter. It is this application that is granted when the patent issues, and which by express provision controls its date. The contention that the original paper called the application is practically a mere introduction of the provisional specification of the British patent law, and that the latter so closely resembles the *caveat* in the United States law (R. S. 4902) that it must, therefore, be regarded merely as its equivalent, in the construction of our statute, is ingenious and plausible, but we cannot accord its soundness.

It may be conceded that the provisional specification which may be first filed with the application in the British Patent Office has some of the features of the *caveat* in our system; but these do not operate to convert the complete specification thereafter to be filed into the application for the patent, within the meaning of section 4867, Revised Statutes, any more than of the British statutes heretofore recited.

Independent of the form or function of either specification that may be filed in connection with, or in support of it, the instrument entitled, and referred to as, the application throughout the British patent law, remains the initiatory step in the proceeding to obtain a patent under that law, and must, therefore, fix the date from which the limitation of section 4867 Revised Statutes begins to run.

The decision appealed from is right and must be affirmed. It is so ordered, and, in addition, that this decision be certified to the Commissioner of Patents as required by law.

Changes in Classification.

(ORDER No. 1,472.)

DEPARTMENT OF THE INTERIOR,
UNITED STATES PATENT OFFICE.

Washington, D. C., May 20, 1902.

The following changes in classification are directed:
In Division V, class 54, Harvesters, the following subclasses are established:

- Binders—
- 190. Sheaf-carriers—
- Automatic-dump,
- Shock-formers—
- 121. Automatic—
- 122. Self-binding,
- 123. Hand.

In Division XXVI, class 173, Electricity, Motive Power, the following subclasses are established:

- Transmission of power—
- Direct—
- 225. Magnetic clutches.

F. I. ALLEN,
Commissioner.

Inks.

(ORDER No. 27.)

All applications, communications, and other instruments in writing or print, which should properly constitute a permanent record in this Office, must be prepared with a substantially permanent ink. Anilin and other perishable inks will not be accepted.

Design Patents.

AN ACT to amend section forty-nine hundred and twenty-nine of the Revised Statutes, relating to design patents.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That section forty-nine hundred and twenty-nine of the Revised Statutes be, and the same is hereby, amended so as to read as follows:

"SEC. 4929. Any person who has invented any new, original, and ornamental design for an article of manufacture, not known or used by others in this country before his invention thereof, and not patented or described in any printed publication in this or any foreign country before his invention thereof, or more than two years prior to his application, and not in public use or on sale in this country for more than two years prior to his application, unless the same is proved to have been abandoned, may, upon payment of the fees required by law and other due proceedings had, the same as in cases of inventions or discoveries covered by section forty-eight hundred and eighty-six, obtain a patent therefor."

Approved May 2, 1902.

Hearings.

DEPARTMENT OF THE INTERIOR,

UNITED STATES PATENT OFFICE,

Washington, D. C., May 16, 1902.

Notice is hereby given that there will be no cases placed upon the docket to be heard by either the Commissioner or the Assistant Commissioner during the months of July and August, 1902.

F. I. ALLEN,
Commissioner.

PATENTS

GRANTED MAY 20, 1902.

700,164. GRINDING ATTACHMENT FOR CARDING-MACHINES. JAMES AUGUSTUS DODGE, Wash. Filed May 22, 1901. Serial No. 41,388. (No model.)

Claim.—1. The combination with a carding-machine provided with a horizontal bed, of a main carding-cylinder covered with carding-cloth, a doffer, a tumbler, and a grinding device permanently located between the doffer and the tumbler and on the tumbler side of the cylinder and therebelow, and means to rotate said grinding device in the same direction with the cylinder, whereby the carding-cloth may be ground while the machine is doing its work.

2. The combination with a carding-machine provided with a horizontal bed, of a main carding-cylinder covered with carding-cloth, a doffer, a tumbler, and a grinding device permanently located between the doffer and the tumbler and therebelow, whereby the carding-cloth may be ground while the machine is doing its work, said grinding device movable to and fro longitudinally of the cylinder, and toward and away from said cylinder.

3. The combination with a carding-machine provided with a horizontal bed, of a main carding-cylinder, a doffer, a tumbler, a rotatable grinding device located between the doffer and the tumbler and therebelow, sliding bearings upon said bed carrying the shaft of said grinding device, bearing-blocks located beneath the sliding bearings, means to adjust the sliding bearings upon said blocks, and means to rotate said grinding device in the same direction with said cylinder, whereby the carding-cloth may be ground while the machine is doing its work.

4. In a carding-machine, the combination with a main carding-cylinder provided with a doffer and with a tumbler, of a grinding device permanently located adjacent to the portion of the cylinder free from the material being carded, between the doffer and the tumbler and therebelow, whereby the cylinder may be ground while the machine is doing its work.

700,165. CRANBERRY-PICKER. CHARLES H. BATHURST, Riverhead, N. Y. Filed Oct. 17, 1901. Serial No. 78,942. (No model.)

Claim.—1. A berry harvester or picker consisting of a single structure including a pan and forwardly-extending fingers said fingers being closed at the bottom and sides and open at the top, and communicating at their rear ends with said pan.

2. A berry harvester or picker consisting of a single structure including a pan having forwardly-extending upturned fingers at the front said fingers having a bottom, sides, and a pointed front end, and being open at the top and having their rear ends open to communicate with the pan.

3. A berry-harvester consisting of a pan or receiver, and fingers at the front portion thereof and closed at the sides and bottom and open at

the top, said fingers having the forward extremities of their sides converging to form a pointed end, and the upper edges of the forward portions of the sides inclining downwardly toward said end, and the rear portions of the fingers communicating with the pan.

700,166. PROJECTILE. OLIVER G. BOWMAN, Clinton, Iowa. Filed Feb. 19, 1902. Serial No. 69,346. (No model.)

Claim.—1. A projectile comprising two sections which are conical and hollow, hinges for joining the sections together and a weighted string secured to one section and wound about said sections for holding them together a predetermined time, and a figure inclosed and carried by the sections, adapted to disintegrate when released, as and for the purpose described.

2. A projectile comprising two conical sections having a circumferential groove, hinges connecting said sections, an elastic connection secured to each of the sections over their hinged portions, a string secured to one of the sections and wrapped in the groove, a weight, a string to which the weight is secured, said string being attached to one of the sections as stated, and a figure inclosed and carried by the projectile.

700,167. SPOOL-HOLDER FOR SEWING-MACHINES. JAMES BOWEN and GEORGE BUCKLEY, Sunderland, England. Filed June 12, 1902. Serial No. 739,086. (No model.)

Claim.—In combination with an arm of a sewing-machine and the spindle thereon to receive a bobbin, a rotatable disk carried by the arm around said spindle and retained stationary by the engagement of a gripping device carried by it with the spindle, a rotatable disk of slightly larger diameter than the bobbin end and located in the recess in the stationary disk, said rotatable disk being provided with a split tube whereby

the bobbin is attached to it, a disk or washer between the bobbin and the rotatable disk and adapted to form a ledge covering the space between the rotatable disk and the fixed disk on which loose coils of thread are received, and a shield or guard carried by the stationary disk and arranged so as to partially surround the rotatable disk and the bobbin for preventing any loose coils forming at the upper part of the bobbin from falling outside of the disks, substantially as described.

700,168. DEHORNING INSTRUMENT. JOHN C. KNOWL, Jerseyville, Ill. Filed Sept. 24, 1900. Serial No. 30,974. (No model.)

Claim.—A dehorning instrument comprising two rectangular frame plates each provided near its center with a rectangular opening having one of its diagonals disposed parallel with the length of the plate, and with two longitudinal slots arranged near one end thereof, and in parallel relation with the sides of the plates, spacing-bars for holding the plates separated at the proper distance apart, the opposed faces of the bars at one end of the plates being formed into racks, and the remainder of the length of each bar being smooth to constitute a guide, a knife having a right-angled recess to coact with the said rectangular openings, and carrying slides to engage the smooth portions of the bars whereby the knife will be guided positively and will be held from any rocking movement, a double-toothed rack-bar carried by the rear portion of the knife and projecting normally beyond the rear ends of the plates, gears meshing with the racks of the spacing-bars and with the double rack-bar, square-shanked studs passing through the said gears and working in the slots in the frame-plates, and bifurcated operating-levers straddling the frame-plates and engaging the said studs, whereby positive pressure will be applied to the said gears equally on both sides thereof, thus to prevent any tendency to lateral strain thereon, which would tend to cause uneven meshing with the racks, substantially as and for the purpose specified.

700,169. INSTRUMENT FOR REMOVING FLOOR-BOARDS SINGLY. JAMES M. CANNACK, Summit, N. J. Filed Jan. 21, 1901. Serial No. 44,064. (No model.)

Claim.—An instrument for removing floor-boards singly, consisting of and comprising, a wooden handle; A, having comparatively thin blade B; and a transverse resistance-plate C, wide enough to resist the thrust of said blade, and the lower end of said handle having haffle-cushions D, substantially as, and for the purposes specified.

700,170. PUMP. JOHN CLANTY, Sellers Grove, Wis. Filed Aug. 17, 1901. Serial No. 73,268. (No model.)

Claim.—1. A deep-well pump comprising a valved piston and a lower valve, a piston-actuating rod extending through the lower valve and its seat, and a rod-supporting spring partially contractive under dead-weight of the piston-rod and column of water in the pump above the piston.

2. A deep-well pump comprising a valved piston and a centrally-open lower valve the seat for which has a central depending barrel, a piston-actuating rod, a barrel-fitting plunger on the rod, and a rod-supporting spring partially contractive under dead-weight of the piston-rod and column of water in the pump above the piston.

3. A deep-well pump comprising a valved piston and a lower valve, a piston-actuating rod extending through the lower valve and its seat, a flanged cup in which the rod is stopped, and a spiral spring having the upper end thereof engaged by the cup, this spring being partially contractive under dead-weight of the piston-rod and column of water in the pump above the piston.

4. A deep-well pump comprising a valved piston and a centrally-open lower valve having a depending tubular shank, a shank-engaging barrel the major portion of which depends from the valve-seat central of same, a plunger in the barrel having a rod provided with a head opposing the piston, and a rod-supporting spring, this spring being contractive under dead-weight of the piston-rod and column of water in the pump above said piston.

5. A deep-well pump comprising a valved piston, and a centrally-open lower valve the seat for which has a central depending barrel, a piston-actuating rod, a barrel-fitting plunger on the rod, a lower spiral spring of less resistance than dead-weight of the piston-rod and column of water in the pump above the piston, a spring-engaging flanged cup in which the plunger-rod is stopped, a housing in which the spring is seated and a circumferentially-apertured coupling connecting the housing with the cage for said valve.

700,171. CASH-REGISTER. JAMES P. ORRILL, Dayton, Ohio, assignor, by mesne assignments, to National Cash Register Company, Jersey City, N. J., a Corporation of New Jersey. Filed Aug. 3, 1900. Serial No. 633,014. (No model.)

Claim.—1. In a cash-register, the combination with two independently-mounted banks of counters, each comprising a series of independent counters, of a registering mechanism, devices for throwing the counters into connection with the registering mechanism, and means connecting the counters of the respective banks whereby when a counter of one bank is brought into connection with the registering mechanism for subsequent operation, the counters of the remaining bank are rendered inoperative in connection with their throwing device.

2. In a cash-register the combination with registering and printing mechanism, of a plurality of special counters arranged to be brought into connection with the registering mechanism at will and means connected to the special counters whereby a special printing device for a certain counter may be operated without throwing the counter into operative position.

3. In a cash-register the combination with a registering mechanism, of a series of counters having special printing devices for designating the operated counters and arranged to be brought into connection with the registering mechanism at will, and means adapted to be operated by a number of said counters for rendering the remainder inoperative in connection with the registering mechanism but operative in connection with the special printing device.

4. In a cash-register the combination with a registering mechanism, of a plurality of counters having special indicators and arranged to be thrown into connection with the registering mechanism at will, and means whereby the indicator of a certain counter may be set without throwing that counter into connection with the registering mechanism.

5. In a cash-register the combination with a registering mechanism, of a counter controlled by a special key, a slide carrying device through which the counter may be thrown into operative position and a second special key arranged to move said slide to prevent the operation of said counter through its key.

6. In a cash-register, the combination with a registering mechanism, of special counters controlled by special keys, a slide arranged to be operated by a number of said keys, and movable counter-throwing devices mounted on said slide and arranged to be operated by a number of said keys so that the counters of said latter keys will be thrown or not according to the position of the slide.

7. In a cash-register the combination with the registering mechanism, of a counter a slide carrying a pivoted pawl, a special key arranged to normally strike said pawl and then throw the counter into connection with the registering mechanism, and another key for moving said slide to remove the pawl out of the path of its keys.

8. In a cash-register the combination with the registering mechanism, of a plurality of special counters keys for bringing said counters into connection with the registering mechanism, a slide for establishing or breaking the connection between a portion of said keys and their counters, and another slide arranged to be operated by a number of the keys and connected to the first-mentioned slide.

9. In a cash-register the combination with the operating mechanism and a counter, a special key or other means for establishing an operative relation between said counter and the operating mechanism, a second counter, a second special key for establishing an operative relation between the second counter and said operating mechanism, a printing device arranged to print whenever said counter is brought into operative relation with the operating mechanism, means controlled by said first-mentioned special key for unlocking the operating mechanism, means controlled by said second special key for disestablishing or preventing operative relation between said first-mentioned counter and the operating mechanism, and a printing device arranged to print whenever said first-mentioned special key is operated.

10. In a cash-register, the combination with a registering mechanism and a totaling-counter, of a series of special counters and their keys, and means co-operating with a number of said special keys whereby when any of the same is operated the counters of the keys not connected to said means are rendered inoperative in connection with their keys without preventing the operation of the latter and the totaling-counter is also rendered inoperative.

11. In a cash-register, the combination with a totaling-counter, of two independent banks of special counters, keys for throwing the counters of the special banks into operative position at will, locking devices for the machine controlled by one of said special banks of keys and means operated by the remaining special bank for throwing the totaling-counter and the counters of the companion special bank out of operative position.

12. In a cash-register, the combination with a registering mechanism, of an indicator, a series of keys, a lever for operating said indicator,

a spring connected to said lever, a stop for limiting the movement of said lever and means connected to the keys for putting the springs under tension to operate the lever and moving said stop.

13. In a cash-register, the combination with a registering mechanism, of a series of flexible shafts operated by the same, special counter-operating devices arranged to be operated by said shafts and means for moving said shafts into or out of connection with said devices.

14. In a cash-register, the combination with a register mechanism, of a series of shafts operated by the same, a movable frame, a series of auxiliary shafts mounted in said frame and flexibly coupled to the first-mentioned shafts special counter-operating devices arranged to be operated by the auxiliary shafts and means for moving the frame to different positions to break or make the connection with the operating devices.

15. In a cash-register, the combination with a registering mechanism, of a series of rack-segments for operating the same, a plurality of flexible shafts having pinions meshing with said segments, a series of special counter-operating gear-wheels, other pinions on the flexible shafts and means for moving said shafts to bring said latter pinions into mesh with the gear-wheels or disengage them from the same.

16. In a cash-register, the combination with a registering mechanism, of a series of keys, a pivoted plate arranged to be engaged by a portion of said keys, pivoted levers adapted to be operated by the remainder of said keys to move the pivoted plate and a printing device arranged to be operated by the pivoted plate being moved different distances by the respective keys.

17. In a cash-register, the combination with a plurality of counters arranged in the banks of an operating mechanism, keys for throwing any one of the counters into mesh with the operating mechanism, and a slide arranged to be operated by the keys of one bank to render the counters of the remaining banks inoperative.

18. In a cash-register, the combination with a plurality of counters arranged in banks, of an operating mechanism, keys for throwing any one of the counters into mesh with the operating mechanism, a slide co-operating with one bank of keys and adapted to be moved by the operation of the same, a second slide co-operating with another bank of keys, counter-operating pawls mounted on said slide and normally lying in the path of the keys and means connecting the two slides whereby the movement of the first-mentioned slide will withdraw the pawls from the paths of their respective keys.

19. In a cash-register the combination with the registering mechanism, of the keys, a detent-plate arranged to engage an operated key and hold it in operative position, means for moving the detent-plate to release the keys near the end of the registering operation, means for locking the detent as soon as said keys are released and for releasing it upon the completion of the registering operation.

20. In a cash-register, the combination with a registering mechanism, of a plurality of keys, a locking frame or detent for said keys, a lock for the registering mechanism means for releasing the locking-frame, devices connecting the locking-frame and lock for operating the latter upon the movement of the former and means for preventing more than one operation of the locking-frame during a single operation of the machine.

21. In a cash-register, the combination with a registering mechanism, of a series of special counters, keys for forcing said special counters into connection with the registering mechanism, a locking frame or detent for said keys and projections on said frame for positively forcing the counters out of connection with the registering mechanism.

22. In a cash-register, the combination with a registering mechanism, of a plurality of keys, a locking frame or detent for said keys, a pivoted arm arranged to be operated by said frame, an independently-movable pawl on said arm adapted to engage said frame, and a machine-locking pawl arranged to be operated by said arm.

23. In a cash-register, the combination with an operating mechanism, of a series of counters, a movable frame having projections which positively force the counters away from the operating mechanism and keys arranged to force the respective counters into engagement with the operating mechanism.

24. In a cash-register, the combination with a plurality of keys, of an indicator, a pivoted lever connected to the same, a rod connected to said lever, a spring surrounding said rod and engaging said lever and means connecting the keys and spring for putting the latter under greater or less tension according to the key operated.

25. In a cash-register the combination with the operating mechanism and a totaling-counter, of two banks of special counters, two banks of special keys for establishing an operative relation between the special counters and the operating mechanism at will, locking devices for the entire operating mechanism controlled by the keys of one of said banks and means operated by the keys of the other bank to prevent or disestablish the operative relation between the counters of said other bank and the operating mechanism.

26. In a cash-register the combination with a plurality of keys, of

an indicator, a spring connected to the indicator, and means connecting the keys and spring whereby the latter is put under different degrees of tension independently of the movement of the indicator to move the latter to a greater or less extent.

37. In a cash-register the combination with a plurality of keys, of an indicator, a spring connected to the indicator, means connecting the keys and spring for putting the latter under different degrees of tension independently of the movement of the indicator, and a locking device for the indicator released by the operation of the machine.

38. In a cash-register the combination with a plurality of keys, of an indicator, a spring connected to the indicator, a stop device connecting the keys and the spring and adapted to put said spring under different degrees of tension independently of the movement of the indicator and also limit the movement of said indicator.

39. In a cash-register the combination with the driving mechanism comprising a segment or its equivalent arranged to receive a differential movement according to the value of the operated key, a series of special counters, a series of gears arranged to actuate the special counters, and a series of flexible shafts each bearing two pinions, one at either end, one of the pinions on each shaft being in permanent mesh with the said segments respectively and the pinions upon the opposite ends of said shafts being arranged to be thrown into or out of engagement with the gears to actuate the special counters, substantially as described.

40. In a cash-register, the combination with the registering mechanism, of a plurality of movable transfer-frames, a plurality of counters, the wheels of which are each provided with a ratchet-wheel, a plurality of transfer-arms arranged to be engaged by said transfer-frames and moved in one direction, pawls mounted on said arms and engaging said ratchet-wheels, and means connected to the counter-wheels for moving said arms positively in an opposite direction.

41. In a cash-register, the combination with a plurality of operating-gears, of a movable frame, operating devices mounted on the frame and arranged to be brought into connection with the gears, locking devices for the operating-gears and means connecting the locking devices and the movable frame so that the locking devices will engage the gears when the operating devices are disengaged from the same and vice versa.

42. In a cash-register the combination with the totalling-counter and normally locked operating mechanism, of a special counter, a special key co-operating therewith to establish an operative relation between said counter and the operating mechanism, a second special counter, a second special key co-operating with said second counter to normally establish an operative relation between said second special counter and the operating mechanism, and means whereby when the said first-mentioned special key is operated subsequently to said second special key the operating mechanism will be thereby unlocked, but said second counter will not be brought into registering relation with the operating mechanism even though its special key remains depressed.

43. In a cash-register the combination with the normally locked operating mechanism, of a special counter, a special key co-operating therewith to bring said special counter into operative relation with the operating mechanism, a second special counter, a second special key co-operating therewith and arranged to bring the same into operative relation with the operating mechanism, and means whereby when the first-mentioned special key is operated subsequently to said second special key the counter which co-operates with said second special key will be brought into operative relation with the operating mechanism, while the counter which co-operates with said first-mentioned special key will be prevented from operative relation with said operating mechanism even though its special key remains depressed.

44. In a cash-register the combination with the registering mechanism and a totalling-counter normally in operative engagement with the registering mechanism, of a special counter and key, a second special counter and key and means whereby when said second special counter is brought into operative relation with the registering mechanism the other special counter and the totalling-counter are both prevented or disconnected from such operative engagement with the registering mechanism even though the key of this latter special counter remains depressed.

45. In a cash-register the combination with operating devices, of a movable frame, a series of shafts mounted on said frame and flexibly connected to said operating devices, gears on said shafts, counter-operating gears and means for moving the frame to bring the gears together or separate them.

46. In a cash-register the combination with operating means, flexible shafts operated by the same, counter-operating devices arranged to be operated by said shafts and means for moving said shafts into or out of connection with said devices.

47. In a cash-register the combination with a registering mechanism of a series of special counters and keys and means connected to a number of said special counters whereby when any one of the same is operated the remaining counters not connected to said means are rendered inoperative irrespective of the action of their keys.

48. In a cash-register the combination with registering and printing mechanism, of a plurality of special counters, keys arranged to cut the respective counters, and also a corresponding printing-type and means for disestablishing the relation between the keys, and the counters so that said keys will cut the types only.

49. In a cash-register the combination with the registering mechanism, of a plurality of independent counters, independent operating-keys for the respective counters, for moving the same into engagement with the registering mechanism, an operating device interposed between one of said keys and its counter for moving the latter and means for withdrawing said device when the other key is operated.

50. In a cash-register the combination with registering and printing mechanisms, of a series of keys arranged to control said registering and printing mechanisms and means whereby said keys may be rendered inoperative as with respect to the registering mechanism but still be capable of controlling the printing.

51. In a cash-register the combination with a series of keys, of a locking-detent for the same, a latch for the machine, a trip-arm for operating said latch arranged to be actuated by the detent, and movable means mounted on said arm and co-operating with the detent to allow movement of the same in one direction but prevent movement in an opposite direction.

52. In a cash-register the combination with a series of keys, of a locking-detent for the same, a latch for the machine, a trip-arm for operating said latch, arranged to be actuated by the detent, and a movable locking device mounted on said arm and arranged to engage the detent after the latter has been operated to prevent a second operation during the same operation of the machine.

53. In a cash-register having a printing attachment, the combination with a special counter, and means to designate by printing upon a paper strip whenever operative relation is established between said special counter and the operating mechanism, of a second counter, and means arranged so that when operative relation is established between the operating mechanism, and said second counter, the first-mentioned counter will be released or held from operative relation therewith, but the said printing means will not be affected thereby.

54. In a cash-register, the combination with registering and printing mechanisms, of a special key controlling a special counter, a second special key controlling both a second counter and printing device, and means whereby upon the first-mentioned special key being operated subsequently to the said second special key, its co-operating printing mechanism will be adjusted to printing position, but operative relation will not be established between its counter and the operating mechanism.

55. In a cash-register, the combination with registering and printing mechanisms, of a special key controlling a special counter, a second special key controlling a special counter, and a co-operating printing device and means whereby when the said second special key is operated previously to the said first-mentioned special key, both the counter controlled by said special key and its printing device will be in operative position, but upon the subsequent operation of said first-mentioned key before the registering mechanism is actuated, the counter co-operating with the said second special key will be released or held from operative position.

56. In a cash-register, the combination with the registering and printing mechanism, of a special key controlling a special counter, a second special key controlling a second special counter and a printing device, and means whereby when said first-mentioned key is operated its co-operating counter will be put into operative relation with the registering mechanism and also the counter controlled by the second special key will be put out of operative relation so that on the subsequent operation of said second key its counter will not be moved into operative relation with the registering mechanism.

57. In a cash-register, the combination with the registering mechanism, and a main or totalling counter, of a special key controlling a counter and an indicator, a second special key controlling a second counter and a second indicator, and means whereby when said first-mentioned key is operated the counter and indicator will be moved or adjusted to operative position and the counter co-operating with said second special key will be moved or held from such operative relation, though its indicator will not be affected.

58. In a cash-register, the combination with the driving mechanism of two banks of special counters, keys for said counters and means connecting said banks and so arranged that the throwing of a counter in one of said banks will prevent an operative relation being established between the counters of the other bank and the registering mechanism without preventing the operation of the keys of this latter bank.

59. In a cash-register, the combination with the registering mechanism of a special key 4 arranged normally to establish an operative relation between its special counter and the registering mechanism, a second special key 3 arranged to do likewise for a second special counter, and means to prevent a subsequent establishment of an operative relation

between the registering mechanism and the special counter until after the registering mechanism has been actuated.

50. In a cash-register, the combination with the registering mechanism, of special keys 4, a counter controlled by the special key 4, a slide 65 carrying operating devices for the counter, and means actuated by a second special key 3, to move the slide and release the counter, substantially as described.

51. In a cash-register, the combination with the registering mechanism, of a counter controlled by a key 4, a slide 65 carrying a pawl or lever 63 arranged to be moved by the key so as to contact with the counter and throw the latter into mesh with the registering mechanism, a special key 3, and means actuated thereby for moving the slide 65 to release the counter.

52. In a cash-register, the combination with the registering mechanism, of the counter normally out of operative engagement with the driving mechanism, means carried on a slide 65 for operating the counter, a special key 3 and a slide 69 arranged to be actuated by the key 3 and to simultaneously move the slide 65 to release the counter from operative relation.

53. In a cash-register, the combination with a registering mechanism and a totaling-counter movable into connection with the registering mechanism, of a special counter, a second special counter similarly movable, and means for throwing the said second special counter into operative engagement with the registering mechanism and for simultaneously releasing the special counter and totaling-counter, or for preventing an operative relation being established between said last-mentioned counter and the registering mechanism prior to the succeeding actuation of the machine.

54. In a cash-register, the combination with a registering mechanism, of a counter and an indicator, a special key controlling the counter and indicator, a second special key controlling a second counter and a second indicator, and means operated by the second special key for preventing the operation of the counter of the first-mentioned key but allowing the operation of its indicator.

55. In a cash-register, the combination with a registering mechanism, of a plurality of counters having special indicators and arranged to be thrown into connection with the registering mechanism at will and a slide operated to prevent certain counters being thrown into connection with the registering mechanism without affecting the setting of the indicators of said counters.

56. In a cash-register, the combination with a registering mechanism, of an indicator, a series of keys, a stop for the indicator arranged to be set by the keys, a spring for operating the indicator also arranged to be set by the keys and means for locking the indicator during the setting movements of the keys and subsequently releasing it upon the operation of the registering mechanism.

57. In a cash-register, the combination with two independently-mounted banks of counters, of counter-operating devices, means for actuating said devices when the counters are moved into connection therewith, and devices connecting the respective banks of counters whereby when a counter in one bank is brought into connection with the operating device the counters in the remaining bank are prevented from being brought into such connection.

700,172. CAR-TRUCK. HOWARD CLAY, Newark, N. J., assignor to Voss and Clay Manufacturing Company, New York, N. Y., a Corporation of New York. Filed Feb. 23, 1900. Serial No. 33,672. (No model.)

Claim.—1. In a truck, the elliptic springs receiving the bolster, a support for said springs, and means connecting said springs with said bolster and said support, said springs each being in two substantially independent halves having pockets in the facing portions of their ends, combined with roller-bearings confined within said pockets and upon which the upper halves of the springs may under the lateral thrusts of said bolster move longitudinally therewith over and independently of the lower halves of said springs, thereby permitting the proper movement of said bolster laterally of the truck-frame; substantially as set forth.

2. In a truck, the series of elliptic parallel springs at each side of the truck to receive the bolster, a support for said springs, and means connecting said springs with said bolster and said support, said springs each being in two substantially independent halves having pockets in the facing portions of their ends, combined with roller-bearings confined within said pockets and upon which the upper halves of the springs may under the lateral thrusts of said bolster move longitudinally therewith over and independently of the lower halves of said springs, thereby permitting the proper movement of said bolster laterally of the truck-frame; substantially as set forth.

3. In a truck, the series of elliptic parallel springs at each side of the truck to receive the bolster, a support for said springs, and means connecting said springs with said bolster and said support, said springs each being in two substantially independent halves having pockets in the

facing portions of their ends, combined with the roller-bearings confined within said pockets and each extending from the pocket of one spring into the adjacent pocket of the adjacent parallel spring, and upon which roller-bearings the upper halves of the springs may under the lateral thrusts of said bolster move longitudinally therewith over and independently of the lower halves of said springs, thereby permitting the proper movement of said bolster laterally of the truck-frame; substantially as set forth.

4. In a truck, the elliptic springs receiving the bolster, a support for said springs, and means connecting said springs with said bolster and said support, said springs each being in two substantially independent halves having pockets in the facing portions of their ends, combined with roller-bearings confined within said pockets and upon which the upper halves of the springs may travel with said bolster, said roller-bearings having heads at their ends to confine and guide them; substantially as set forth.

5. In a truck, the elliptic springs receiving the bolster, a support for said springs, and means connecting said springs with said bolster and said support, said springs each having elongated concave pockets with curved end portions in the facing sides of their ends, combined with roller-bearings confined within said pockets and upon which the upper halves of the springs may under the lateral thrusts of said bolster move longitudinally therewith over and independently of the lower halves of said springs, thereby permitting the proper movement of said bolster laterally of the truck-frame; substantially as set forth.

6. In a truck, the elliptic springs receiving the bolster, a support for said springs, and means connecting said springs with said bolster and said support, said springs each being in two substantially independent halves, combined with roller-bearings confined between the facing sides of the ends of said springs and upon which the upper halves of the springs may under the lateral thrusts of said bolster move longitudinally therewith over and independently of the lower halves of said springs, thereby permitting the proper movement of said bolster laterally of the truck-frame; substantially as set forth.

7. In a truck, the elliptic springs receiving the bolster, a support for said springs, and means connecting said springs with said bolster and said support, said springs each being in two substantially independent halves, combined with bearings confined between the facing sides of the ends of said springs and upon which the upper halves of the springs may under the lateral thrusts of said bolster move longitudinally therewith over and independently of the lower halves of said springs, thereby permitting the proper movement of said bolster laterally of the truck-frame; substantially as set forth.

700,178. LAWN-MOWER. HOWARD E. CLAYTON, Lansdale, Pa. Filed Aug. 17, 1901. Serial No. 72,368. (No model.)

Claim.—1. In a mowing-machine the combination of a frame having a drive-wheel held thereon, a finger-bar held on the forward portion of the frame, a cutter-bar positioned thereon, springs held on the frame

and adapted for engagement with the cutter-bar, a spring-bar carried by the cutter-bar and adapted for engagement with the finger-bar, balls interposed between the said springs and bars, substantially as shown and described.

2. In a cutter apparatus for moving-machines, the combination of a finger-bar having slots arranged therein, a cutter-bar arranged upon the finger-bar, a flat spring having its ends protruding through the slots in the said finger-bar and having a recess arranged in its upper face, and an anti-friction-ball held in the said recess and adapted to bear against the said finger-bar whereby the said bars are held together, substantially as shown and described.

3. In a moving-machine, the combination of a frame having a finger-bar secured thereto, of a cutting-bar held upon the said finger-bar, springs carried by the said frame and having their forward ends enlarged and recessed, anti-friction-balls held in the said recesses and adapted to bear against the said cutter-bar, the said cutter-bar having slots adapted to receive studs arranged on the said finger-bar and means carried by the said frame for operating the cutter-bar, substantially as shown and described.

4. In a moving-machine, the combination of a frame, a drive-wheel journaled therein, supporting-wheels journaled in the said frame, a cutting device arranged on the said frame in advance of the said supporting-wheels, springs held upon the journals of the supporting-wheels, and having one end engaging the cutting device, and the opposite ends engaging the frame, substantially as shown and described.

5. In a moving-machine, the combination of a frame, having a bracket held thereon, a drive-wheel having gear-teeth journaled in the said frame, a shaft carrying a sprocket-wheel and cam-wheel journaled in the said frame and bracket, supporting-wheels journaled on the said frame, a finger-bar arranged on the said frame in advance of the said supporting-wheels, the said bar having longitudinal slots arranged therein, a cutting-bar having a spring-bar held thereto, the ends thereof protruding through the said slots, an anti-friction-ball interposed between the said spring-bar and finger-bar, the said cutting-bar also having slots adapted to receive studs carried by the said finger-bar, springs coiled upon the journals of the said supporting-wheels, each having one end held to the frame, the opposite end thereof having a socket formed therein and adapted to hold an anti-friction-ball, the said balls engaging the cutting-bar, and a lever held in a bracket carried by the frame, and adapted for engagement with the said cam-wheel and cutting-bar, substantially as shown and described.

6. In a cutting device for moving-machines, the combination of a finger-bar and cutter-bit, each having a recess formed in their contiguous surfaces and near their rear edges, anti-friction-balls held in the said recesses and of such size as to separate the said bars at the rear edges and throw the opposite edges into contact, substantially as shown and for the purposes specified.

700,174. CANNETT-BENEL. ROBERT J. CUPPLAND, Toronto, Canada.
Filed July 8, 1899. Serial No. 728,128. (No model.)

Claim.—1. A cabinet-desk comprising a desk-top, and a moving bookcase having a series of book-compartments, the desk-top and bookcase being so combined and arranged that the bookcase may be moved so as to bring its compartments on a level with the desk-top, and means for holding the books on the desk-top to prevent the removal of the books therefrom except into the bookcase.

2. A cabinet-desk comprising a desk-top, and a vertically-moving bookcase having a series of book-compartments, the desk-top and bookcase being so combined and arranged that the bookcase may be moved so as to bring its compartments on a level with the desk-top, and means for holding the books on the desk-top to prevent the removal of the books therefrom except into the bookcase.

3. A cabinet-desk comprising a desk-top, and a moving bookcase having a series of book-compartments, the desk-top and bookcase being

so combined and arranged that the bookcase may be moved so as to bring its compartments on a level with the desk-top, means to prevent the removal of a book when not on a level with the desk-top, and means for holding the books on the desk-top to prevent the removal of the books therefrom except into the bookcase.

4. A cabinet-desk comprising a desk-top, and a vertically-moving bookcase having a series of book-compartments, the desk-top and bookcase being so combined and arranged that the bookcase may be moved so as to bring its compartments on a level with the desk-top, means to prevent the removal of a book when not on a level with the desk-top, and means for holding the books on the desk-top to prevent the removal of the books therefrom except into the bookcase.

5. A cabinet-desk comprising a desk-top, a cord, and a vertically-moving bookcase suspended behind the desk-top by said cord and having a series of book-compartments, the desk-top and bookcase being so combined and arranged that the bookcase may be moved so as to bring its compartments on a level with and opposite the desk-top, and means for holding the books on the desk-top to prevent the removal of the books therefrom except into the bookcase.

6. A cabinet-desk comprising a desk-top, a cord, and two moving bookcases suspended on opposite ends of said cord and having a series of book-compartments, the desk-top and bookcases being so combined and arranged that the bookcase may be moved so as to bring their compartments on a level with and opposite the desk-top, means to prevent the removal of a book when not on a level with and opposite the desk-top, and means for holding the books on the desk-top to prevent the removal of the books therefrom except into the bookcase.

7. A cabinet-desk comprising a desk-top, a cord, and two vertically-moving bookcases suspended on the opposite ends of said cord behind and facing the desk-top so as to move simultaneously in opposite directions, and each having a vertical series of book-compartments.

8. A cabinet-desk comprising a desk-top, a cord, and two vertically-moving bookcases suspended on the opposite ends of said cord behind and facing the desk-top so as to move simultaneously in opposite directions, and each having a vertical series of book-compartments, and means to prevent the removal of a book when not on a level with and opposite the desk-top.

9. A cabinet-desk comprising a desk-top, a cord, and two vertically-moving bookcases suspended on the opposite ends of said cord behind and facing the desk-top so as to move simultaneously in opposite directions, and each having a plurality of vertical series of book-compartments, and a stationary casing including the moving bookcases.

10. A desk-top having one or more ways in which a book may move back and forth, and having means constructed to engage each book to prevent it from being lifted from the desk-top.

11. A cabinet-desk comprising a desk-top having one or more ways in which a book may move back and forth, and having means constructed to engage each book to prevent it from being lifted from the desk-top; and a moving bookcase having a series of book-compartments, the desk-top and bookcase being so arranged that the bookcase may be moved so as to bring its compartments on a level with the desk-top and in line with the ways therein, whereby the books of the different compartments may be removed from their compartments directly to a way of the desk-top or the reverse.

12. A cabinet-desk comprising a desk-top having one or more ways in which a book may move back and forth, and having means constructed to engage each book to prevent it from being lifted from the desk-top; and a moving bookcase having a series of book-compartments, the desk-top and bookcase being so arranged that the bookcase may be moved so as to bring its compartments on a level with the desk-top and in line with the ways therein, whereby the books of the different compartments may be removed from their compartments directly to a way of the desk-top or the reverse, and means to prevent the removal of a book from its compartment except to a way of the desk-top.

13. A cabinet-desk comprising a desk-top having one or more ways in which a book may move back and forth, and having means constructed to engage each book to prevent it from being lifted from the desk-top; and a vertically-moving bookcase arranged behind the desk-top and having a series of book-compartments, the desk-top and bookcase being so arranged that the bookcase may be moved so as to bring its compartments on a level with the desk-top and in line with the ways therein, whereby the books of the different compartments may be removed from their compartments directly to a way of the desk-top or the reverse.

14. A cabinet-desk comprising a desk-top having one or more ways in which a book may move back and forth, and having means constructed to engage each book to prevent it from being lifted from the desk-top; and a moving bookcase suspended behind the desk-top by a cord and having a series of book-compartments, the desk-top and bookcase being so arranged that the bookcase may be moved so as to bring its compartments on a level with the desk-top and in line with the ways therein, whereby the books of the different compartments may be removed from their compartments directly to a way of the desk-top or the reverse.

15. A cabinet-desk comprising a desk-top having one or more ways in which a book may move back and forth, and having means constructed to engage each book to prevent it from being lifted from the desk-top; and a vertically-moving bookcase arranged behind the desk-top and having a series of book-compartments, the desk-top and bookcase being so arranged that the bookcase may be moved so as to bring its compartments on a level with the desk-top and in line with the ways therein, whereby the books of the different compartments may be removed from their compartments directly to a way of the desk-top or the reverse, and means to prevent the removal of a book from its compartment except to a way of the desk-top.

16. A cabinet-desk comprising a desk-top having one or more ways in which a book may move back and forth, and having means constructed to engage each book to prevent it from being lifted from the desk-top; and a vertically-moving bookcase suspended behind the desk-top by a cord and having a series of book-compartments, the desk-top and bookcase being so arranged that the bookcase may be moved so as to bring its compartments on a level with the desk-top and in line with the ways therein, whereby the books of the different compartments may be removed from their compartments directly to a way of the desk-top or the reverse, and means to prevent the removal of a book from its compartment except to a way of the desk-top.

17. The combination of a bookcase and a desk-top with books designed to fit in the bookcase and be removable therefrom upon the desk-top, said books and the desk-top having interlocking means whereby when a book is removed from its case upon the desk-top it enters into engagement with the desk-top, and means to prevent the removal of a book from its case except upon the desk-top.

18. The combination of a bookcase and a desk-top with books designed to fit in the bookcase and be removable therefrom upon the desk-top, the books of said books and the desk-top having interlocking means whereby when a book is removed from its case upon the desk-top it enters into engagement with the desk-top, and means to prevent the removal of a book from its case except upon the desk-top.

19. A closed casing having a moving bookcase therein and provided with an opening through which books in the moving case may be withdrawn, in combination with a desk-top arranged in proximity to said opening and having means to engage the books when withdrawn from their case and so prevent the removal of the books from the desk-top except into the bookcase.

20. The combination of a bookcase having a series of book-compartments and a desk-top, the bookcase and desk-top being arranged for changing their relative position so that the desk-top may come into proper position with respect to the book-compartments for the withdrawal of the books from said compartment directly upon the desk-top, the desk-top being provided with means for engaging the books to prevent their removal from the desk-top except into the bookcase.

21. The combination of a bookcase having a series of book-compartments and a desk-top, the bookcase and desk-top being arranged for changing their relative position so that the desk-top may come into proper position with respect to the book-compartments for the withdrawal of the books from said compartment directly upon the desk-top, means for connecting the books with the desk-top to prevent the books from being lifted

from the desk-top, and means to bar the withdrawal of a book from its compartment except into connection with the desk-top.

22. A cabinet-desk comprising a desk-top, and a moving bookcase having a series of book-compartments, said compartments being formed in one or more separate removable cases, the desk-top and bookcase being so combined and arranged that the bookcase may be moved so as to bring its compartments on a level with the desk-top, the desk-top being provided with means for engaging the books to prevent their removal from the desk-top except into the bookcase.

23. A cabinet-desk comprising a desk-top, and a moving bookcase having a series of book-compartments, said compartments being formed in one or more separate removable cases, the desk-top and bookcase being so combined and arranged that the bookcase may be moved so as to bring its compartments on a level with and opposite the desk-top, and means to prevent the removal of a book when not on a level with the desk-top, the desk-top being provided with means for engaging the books to prevent their removal from the desk-top except into the bookcase.

24. A cabinet-desk comprising a desk-top, and two vertically-moving bookcases suspended on the opposite ends of a cord behind the desk-top and each having a series of book-compartments, said compartments being formed in one or more separate removable cases, and means to prevent the removal of a book when not on a level with the desk-top, the desk-top being provided with means for engaging the books to prevent their removal from the desk-top except into the bookcase.

25. A cabinet-desk comprising a desk-top having one or more ways in which a book may move back and forth, and having means constructed to engage each book to prevent it from being lifted from the desk-top; and a vertically-moving bookcase arranged behind the desk-top and having a series of book-compartments, said compartments being formed in one or more separate removable cases, the desk-top and bookcase being so arranged that the bookcase may be moved so as to bring its compartments on a level with the desk-top and in line with the ways therein whereby the books of the different compartments may be removed from their compartments directly to a way of the desk-top or the reverse, and means to prevent the removal of a book from its compartment except to a way of the desk-top.

26. The combination of a desk-top, a book movable thereon, and interlocking means adapted and designed to movably connect the book with the desk-top and prevent it from being lifted therefrom.

27. The combination of a desk-top, a book movable thereon, and interlocking means adapted and designed to movably connect the book with the desk-top and prevent it from being lifted therefrom, and a bookcase to receive the book and having means to prevent the removal of the book, except into connection with the desk-top so as to connect the books with the desk-top.

700,175. AUTOMOBILE. CHARLES CURTIS, Shannon, Ill. Filed Oct. 5, 1900. Serial No. 32,111. (No model.)

Claim.—1. In a vehicle, the combination with a suitable running-gear, of an axle, a bearing-ring vertically pivoted upon the axle, a wheel journaled upon the bearing-ring and having a portion extending within the case, a driving-shaft and a universal joint connecting the driving-

shaft to the hub within the ring concentric with the wheel and substantially in the pivotal axis of the ring; substantially as described.

2. The combination with an axle, a bearing-ring diametrically pivoted to the axle, the hub, H, journaled upon the bearing-ring, and having the inwardly-curved web, A', the shaft, I, journaled in the axle and having the forked collar, K, and the bearing-block, J, in the pivotal axis of the ring and the center of the hub, said block being provided with pivot-pins pivoted to the hub and collar respectively at right angles to each other, with a washer for clamping said pins in place and means for securing the washer tightly upon said pins; substantially as described.

3. The combination, in a four-wheeled vehicle, of a suitable framework, front and rear wheels, devices for turning both front and rear wheels with relation to the framework to steer the vehicle and means for disengaging one set of wheels from the steering devices and engaging them with other portions of the vehicle, so as to prevent their oscillation with respect to the vehicle; substantially as described.

4. In a vehicle, the combination with the body, and front and rear wheels, adapted to be operated to steer the vehicle, of the rock-shaft, O', connected at its respective ends to the front and rear wheels and provided with a clutch adapted to engage that portion of the shaft which is connected to one set of wheels, alternately with the other portion and with the vehicle and steering devices connected with said other portion and adapted to rock the shaft; substantially as described.

5. In a driving-gear for a four-wheeled vehicle, the combination with a divided driving-shaft, of a loose driving-wheel at the point of division, radially-journaled pinions in said driving-wheel, gears secured to the two portions of the shaft and meshing with said pinions, brake-wheels upon the respective portions of the shaft containing radial pinions, loose gears upon the opposite sides of said brake-wheels, meshing with the pinions in the latter, suitable connections between said loose gears and the respective four wheels of the vehicle and suitable brakes applied to the brake-wheels; substantially as described.

700,176. STOOL OR BENCH. BENJAMIN R. GARDNER, Providence, R. I. Filed July 2, 1901. Serial No. 98,308. (No model.)

Claim.—A stool consisting of the combination of a tubular barrel, two heads having central apertures of the same diameter as the inside of said barrel, bushings fitting tightly in said barrel, and having inwardly-beveled heads cut down to the level of the surface of the bushing on one or more sides to form projections, there being recesses made in the outside of each head around the hole to receive these parts of the head of the bushing not cut away, substantially as described.

700,177. SWEATER-GARMENT. BENJAMIN H. GROSS, Utica, N. Y., assignor to Avalon Knitwear Company, Utica, N. Y. Filed Mar. 15 1900. Serial No. 98,309. (No model.)

Claim.—The combination in a sweater garment consisting of the upper band portion of the forward and rear parts separated by side vents and provided with button or other detachable connecting devices at said vents, the said rear part consisting of overlapping flaps, strings attached to the edges of said flaps and passing through eyes in the band of said rear portion adjacent to said side vents, and brought to the rear and tied, substantially as set forth.

700,178. DEVICE FOR ASSEMBLING THE ROLLERS OF ROLLER-BEARINGS. EDGAR F. CROFTON, Vicksburg, Miss. Filed Aug. 28, 1901. Serial No. 72,918. (No model.)

Claim.—1. A device for the purpose described comprising two connected heads, each of which is made in two separable parts having a central recess and provided with inward-extending pins, and means for adjusting one of said heads toward and from the other.

2. A device for the purpose described comprising two connected heads, each of which is made in two separable parts having a central recess and provided with inward-extending pins, the pins on one head being yielding.

3. A device for the purpose described comprising two connected heads, each of which is made in two separable parts having a central recess and provided with inward-extending pins, the pins on one head being yielding, and means for adjusting one of said heads toward and from the other.

4. A device for the purpose described comprising two connected heads, each of which is made in two separable parts having a central recess and provided with inward-extending pins, the pins on one head being yielding, and a series of pointed thumb-screws carried by each head.

5. A device for the purpose described comprising two connected heads, each of which is made in two separable parts having a central recess and provided with means for detachably engaging a series of rollers.

6. A device for the purpose described comprising two connected heads, each of which is made in two recessed parts having a hinge connection and provided with means for detachably engaging a series of rollers.

7. A device for the purpose described comprising two connected heads each of which is made in two separable parts having a central recess, one of said heads carrying a series of stationary pins and the other of said heads comprising connected parallel plates having a series of spring-controlled pins mounted thereon.

8. A device for the purpose described comprising two connected heads each of which is made in two separable parts having a central recess, one of said heads carrying a series of stationary pins and pointed thumb-screws and the other of said heads comprising connected parallel plates having a series of spring-controlled pins and a series of pointed thumb-screws mounted thereon.

9. A device for the purpose described comprising two heads each of which is made in two separable parts having a central recess, a series of inward-extending pins carried by each of said heads, one of said heads being provided on opposite sides with apertures, bars connected at one end to opposite sides of the other head and having their opposite ends passed through said apertures, and set-screws for engaging each end, whereby one of said heads may be adjusted toward and from the other.

10. A device for the purpose described comprising two connected heads each of which is made in two separable parts, one of said heads carrying a series of stationary pins and the other of said heads comprising a flanged plate having screw-threaded pins extending outward from its flange, a cover-plate resting on said flange and apertured to pass over said pins, nuts on said pins for securing the cover-plate in place, and a series of spring-controlled pins mounted in said plates, the combination operating as set forth.

11. In a device for the purpose described, the combination with the head 2 carrying the fixed pins, the head 1 comprising connected parallel plates having screw-threaded and non-circular apertures, respectively, and a coiled spring located between said plates and having at one end a screw-threaded projection engaging in said screw-threaded aperture and at its opposite end a pointed non-circular projection extending through said non-circular aperture, substantially as described.

700,179. JOURNAL-BOX AND ROLLER-BEARING FOR RAILWAY-CAR AXLES. EDGAR F. CROFTON, Vicksburg, Miss. Filed Aug. 28, 1901. Serial No. 72,909. (No model.)

Claim.—1. The combination with a railway-car axle having a circumferential groove near its end and having the edge of its end rounded, of a plurality of rollers arranged around the axle and having enlarged concave shoulders on their opposite ends which overhang the rounded end

of the axle and engage said circumferential groove, said concave shoulders diverging from the adjacent portions of the axle, and a casing including said rollers, substantially as described.

2. The combination with a railway-car axle having a circumferential groove near its end and having the edge of its end rounded, of a series of rollers arranged around the axle and having enlarged concave shoulders at their opposite ends which overhang the rounded end of the axle and engage said circumferential groove, a second series of rollers arranged around and contacting with the first-named series and having rounded ends lying between the enlarged concave shoulders of the first-named rollers, said rounded ends and concave shoulders diverging from one another, and a casing including said rollers, substantially as described.

3. The combination with a railway-car axle having a circumferential groove near its end and having the edge of its end rounded, of a series of rollers arranged around the axle and having enlarged concave shoulders at their opposite ends which overhang the rounded end of the axle and engage said circumferential groove, a second series of rollers arranged around and contacting with the first-named series and having rounded ends lying between the concave shoulders of the first-named rollers, and a contractible sleeve including said rollers and provided with inwardly-projecting concave shoulders on its opposite ends which overhang the rounded ends of the outer rollers, said rounded ends and concave shoulders diverging from one another, substantially as described.

4. The combination with a railway-car axle having a circumferential groove near its end and having the edge of its end rounded, of a series of rollers arranged around the axle and having enlarged concave shoulders at their opposite ends which overhang the rounded end of the axle and engage said circumferential groove, a second series of rollers arranged around and contacting with the first-named series and having rounded ends lying between the concave shoulders of the first-named rollers, and a contractible sleeve including said rollers and comprising a plurality of segmental sections provided on their adjacent edges with interlocking tongues, the ends of said sections having inwardly-projecting concave shoulders overhanging the rounded ends of the outer rollers, substantially as described.

5. The combination with a railway-car axle, of a plurality of rollers arranged around the axle, a contractible sleeve surrounding said rollers and comprising a plurality of segmental sections provided on their adjacent edges with interlocking tongues, a two-part journal-box including said sleeve, and means for clamping said two-part box about the sleeve, substantially as described.

6. The combination with a railway-car axle, of a journal-box mounted on the axle and comprising two half-boxes, said half-boxes being provided on their inner-adjacent edges with vertically-projecting and interlocking slotted lugs, tapered lugs loosely fitted in said slotted lugs, means for adjusting said lugs endwise in said lugs to draw the half-boxes together, and means for yieldingly holding said lugs in their adjusted positions whereby they will be automatically tightened in said lugs to compensate for wear of the parts, substantially as described.

7. The combination with a railway-car axle, of a journal-box mounted on the axle and comprising two half-boxes provided on their inner-adjacent edges with vertically-projecting and interlocking slotted lugs, tapered lugs fitted loosely in said slotted lugs and provided at their smaller ends with threaded stems, nuts screwed over said stems, and coiled springs arranged on said stems between said nuts and the adjacent lugs, substantially as described.

8. The combination with a railway-car axle, of a journal-box mounted on the axle and comprising two half-boxes provided on their adjacent edges with vertically-projecting slotted lugs, the lugs of one half-box loosely fitting between the corresponding lugs of the other box, and said inner-adjacent edges of the boxes being mortised upon their inner sides between the lugs for the reception of the ends of the opposing lugs, tapered lugs fitted in the slotted lugs, means for adjusting said lugs endwise in the lugs to draw the half-boxes together, and springs arranged to automatically draw said lugs tightly to their ends in the lugs to compensate for wear of the parts, substantially as described.

9. The combination with a railway-car axle, of a journal-box mounted on the axle and comprising two half-boxes provided with means for clamping them about the axle, the inner face of one of said half-boxes being provided with longitudinal grooves near its edge for the reception

of a fibrous packing and the inner face of the other half-box being provided with longitudinal serrated ribs arranged to project into said grooves and engage and hold the packing against displacement, substantially as described.

10. The combination with a railway-car axle, of a journal-box mounted on the axle and comprising two half-boxes provided with means for clamping them about the axle, said half-boxes being provided on their adjacent faces with conical recesses for the reception of a sleeve and at their ends with inwardly-projecting semi-circular flanges including said sleeve, the inner face of one of said boxes being provided with longitudinal grooves for the reception of a fibrous packing, and the inner face of the other half-box being provided with longitudinal serrated ribs arranged to project into said grooves and engage and hold the packing, and antifriction-rollers arranged in the box between said flanges, substantially as described.

11. The combination with a railway-car axle, of a journal-box comprising two half-boxes provided with means for clamping them about the axle, said half-boxes being provided on their opposite ends with continuous grooves for the reception of fibrous packing, and end caps fitted against the ends of the half-boxes and provided on their inner faces with serrated ribs projecting into said grooves and engaging and holding the packing therein, substantially as described.

12. The combination with a railway-car axle, of a journal-box comprising two half-boxes provided with means for clamping them about the axle, and caps clamped against the ends of the half-boxes, the outer end cap being imperforate and the inner end cap being provided centrally with an aperture for the reception of the axle, the wall of said aperture being provided with an internal annular groove for the reception of fibrous packing, and transverse ribs formed in the bottom of said groove, substantially as described.

700,180. COMBINED RAD-IRON AND VAPOR-STOVE. JAMES H. GUNTER, Louisville, Ky., assignor of one-third to Clarence Hale, Louisville, Ky. Filed June 7, 1901. Serial No. 62,575. (No model.)

Claim.—1. A combined rad-iron and vapor-stove, comprising a base, and a burner secured to the base and consisting of an outer bifurcated casing having longitudinal upper and lower slots, and an inner cylinder having rows of perforations and rotatable and fitting snugly within the bifurcated casing so as to expose the rows of perforations to either of the longitudinal slots.

2. A combined rad-iron and vapor-stove, comprising a base, and a burner secured to the base and consisting of an outer bifurcated casing having longitudinal upper and lower slots, and a transverse slot, and an inner cylinder, having rows of perforations and a lower working in the transverse slot, whereby the inner cylinder is adapted to be rotated so as to expose the rows of perforations to either of the longitudinal slots.

700,181. PROCESS OF REFINING OIL. EDWARD DUBILLET, La Garenne-Colombe, France. Filed June 14, 1901. Serial No. 64,466. (No specimens.)

Claim.—1. A process for refining oil and the like, which consists in passing a current of alcohol vapors through the oil, then in passing a current of steam through the oil, and finally in filtering the oil so treated, substantially as described.

2. The process for refining oil and the like, which consists in dis-

oil in basin, passing successive currents of alcoholic vapors and a current of steam and in filtering the oil after said treatment, substantially as described.

700,182. BRUSH-HOLDING RING FOR DYNAMOS OR MOTORS.
FREDERICK R. DUNCAN, Akron, Ohio. Filed Feb. 21, 1900. Serial No. 25,127. (No model.)

Claim.—1. The combination in a dynamo or motor, with the case and brush, of a rabbeted groove in said brush concentric with the axis of the armature, an opening into said groove, and a toothed ring resting in said groove bearing brush-rod, substantially as shown and for the purpose specified.

2. The combination in a dynamo or motor and brush of a rabbeted groove in said brush concentric with the axis of the armature, an opening into said groove, a reversible toothed ring resting in said groove bearing insulated brush-supporting rods, and bushings mounted on said rods, substantially as and for the purpose specified.

700,188. WHEEL. JOHN DE ROUX, Uniontown, Pa. Filed Aug. 2, 1900. Serial No. 25,733. (No model.)

Claim.—1. In a wheel, a hub, an oil-box surrounding the hub, longitudinal partitions in said oil-box dividing the same into a series of completely closed compartments excepting that there are contracted oil passages or ports formed in each of the partitions at the base thereof which constitute the only means of communication between said compartments, the floor of one or more of the compartments having a contracted opening for feeding oil to the axle, and means by which the oil-box may be supplied with oil; substantially as described.

2. In a wheel, a rim, a hub, an oil-box surrounding said hub, spokes connecting said oil-box and rim, the spokes extending through the oil-box and dividing the same into a series of completely closed compartments excepting that there are contracted oil passages or ports formed in each of the spoke extensions which constitute the only means of communication between said compartments, the floor of one or more of the compartments having a contracted opening for feeding oil to the axle, and means by which the oil-box may be supplied with oil; substantially as described.

700,184. GEAR-CUTTING ENGINE. FRED L. SHREVE and HENRY F. SHREVE, Newark, N. J., assignors to Gould & Macfarland, Newark, N. J., a Corporation of New Jersey. Filed May 3, 1901. Serial No. 25,194. (No model.)

Claim.—1. A gear-cutter having the horizontal bed *a*, the table *c* adjustable upon the bed, the hinge-plate *d* jointed upon the table and the outer-plate *e* pivoted upon said hinge-plate, the bearing *g* attached to said table and supporting the driving-shaft *f* in line with the joint of the hinge-plate, a horizontal bearing *g'* connected with the bearing *g* and a horizontal driving-shaft *h* on the shaft *f* extended through said bearing and

connected by gearing with the shaft *f*, whereby the motion of the driving-shaft can be imparted to the cutter when the hinge-plate is adjusted at various angles upon the table, substantially as herein set forth.

2. A gear-cutter having a table with a hinge-plate jointed thereon and supporting a cutter-plate with a cutter-head and feed-gearing for reciprocating the same, a bearing attached to the table with a driving-shaft in line with the joint of the hinge-plate, and a train of gearing connecting the driving-shaft with the feed-gearing and with the cutter-spindle, as and for the purpose set forth.

3. A gear-cutter having gearing with change-wheels to control the shifting of the blank, a bed with table adjustable upon the bed, a hinge-plate jointed upon the table, with a cutter-plate supported upon said hinge-plate and a cutter-head movable upon the slide carrying a cutter-spindle and cutter to cut the blank, a bearing fixed to the table and supporting a driving-shaft in line with the joint of the hinge-plate, and separate trains of gearing connecting the driving-shaft respectively with the cutter-spindle and with the change-wheels to control the shifting of the blank.

4. A gear-cutter having gearing with change-wheels to control the shifting of the blank, a bed with table adjustable upon the bed, a hinge-plate jointed upon the table with outer-plate supported upon said hinge-plate, and a cutter-head movable upon the slide carrying a cutter-spindle and cutter to cut the blank, a screw with gearing to reciprocate the cutter-head, a bearing fixed to the table and supporting a driving-shaft in line with the joint of the hinge-plate, and separate trains of gearing connecting the driving-shaft respectively with the cutter-spindle, the feed-screw of the cutter-head, and the change-wheels to control the shifting of the blank.

5. A gear-cutter having gearing with change-wheels to control the intermittent shifting of the blank, a bed *a* with table *c* adjustable upon the bed, the outer-plate *e* pivoted upon the table and adjustable angularly, the outer-head *i* movable upon the slide and carrying the cutter-spindle *j*, the feed-screw *k* with gearing at the outer end of the outer-plate to reciprocate the cutter-head, the bearing *d'* attached to the table and supporting the shaft *l* parallel with the side of the table, a train of gearing connecting said shaft with the change-wheels to control the intermittent shifting of the blank, and a separate train of gearing connecting the shaft with the feed-screw *k*, and provided with the universal joint *l'* to compensate for the angular adjustment of the outer-plate, substantially as set forth.

6. A gear-cutter having gearing with change-wheels to control the shifting of the blank, the table *c* adjustable upon the bed *a*, the outer-plate *e* pivoted upon the table *c* and adjustable angularly, the outer-head *i* movable upon the slide and carrying the cutter-spindle *j*, the feed-screw *k* with gearing at the outer end of the outer-plate to reciprocate the cutter-head, the horizontal bearings *g* and *d'* attached to the table, with the driving-shaft *f* supported in the bearing *g*, and the shaft *l* supported in the bearing *d'* and connected with the shaft *f*, and having the universal joint *l'* connected with the feed-screw gearing, the bearings *g* and *d'* connected

with the bearing *g*, and the shaft *i* mounted in the bearing *g'* and connected with the shaft *e*, the whole arranged and operated substantially as herein set forth.

7. A gear-cutting, having the bed *a* and column *b* with means to support and rotate the blank, the table *c* adjustable upon the bed, the hinged plate *d* with joint *e* upon the table, the segments *f* with gearing to elevate the hinged plate, the bearing *g* secured to the table in line with the joint *e* for carrying the driving-shaft, the outer-slide and outer-head supported upon the hinged plate, and separate trains of gearing connecting the driving-shaft *e* respectively with the change-wheels to control the shifting of the blank, and with the cutter, substantially as herein set forth.

8. A gear-cutting having the bed *a* with table *c* adjustable thereon, and provided with joint *e* and bearing *g* carrying the driving-shaft *e'* in line with the joint *e*, the hinged plate *d* having the outer-slide *k* adjustably pivoted thereon, the outer-head *i* carrying outer-spindle *j*, the feed-screw *h* with gearing at its forward end to reciprocate the outer-head, and the shaft *l* having the bearing *d'* upon the hinged plate, and the bearing *h'* upon the outer-slide and provided with the universal joints as set forth, connections between the shaft *l* and the feed-screw gearing, and gearing connecting the same shaft with the outer-spindle *j*, whereby the outer-slide may be adjusted laterally and the hinged plate adjusted vertically and the moving parts driven by connection with the shaft *e'*.

9. A gear-cutting adapted for cutting worm-gears and bevel-gears as set forth, and having the bed *a*, the adjustable table *c*, the hinged plate *d*, the outer-slide *k* and the outer-head *i* carrying the spindle *j*, the bearing *g* fixed upon the table and carrying the driving-shaft *e* in line with the joint of the hinged plate, a train of gearing connecting the driving-shaft with the outer-spindle, and change-wheels, as *m*, interposed in such train to vary the speed of the outer-spindle, as and for the purposes set forth.

10. A gear-cutting having a worm-wheel, a worm and change-wheels to control the shifting of the blank, and provided with the bed *a*, the adjustable table *c*, the hinged plate *d* jointed to the table, the outer-slide *k* and the outer-head *i* carrying the spindle *j*, the bearing *g* fixed upon the table and carrying the driving-shaft *e* in line with the joint of the hinged plate, a train of gearing connecting the said driving-shaft with the worm, and change-wheels interposed between the driving-shaft and worm, to vary the speed of the worm in shifting the blank.

11. A gear-cutting having the bed *a* and column *b* with mandrel-bearing supporting worm-wheel and worm *n* as set forth, the table *c* adjustable upon the bed, the hinged plate *d* with joint *e* upon the table and the outer-head and slide supported upon the hinged plate as set forth, the bearing *g* secured to the table in line with the joint *e* for carrying the driving-shaft *e'*, and a train of gearing connecting the driving-shaft with the worm and including the horizontal shaft *i* adapted to slip through one of the driving-wheels to compensate for the various adjustments of the table *c* upon the bed.

12. A gear-cutting having a horizontal bed supporting a outer-slide with a outer-head movable upon the same and feed-gearing for reciprocating the head, the gear-case *h'* upon the forward end of the slide containing the feed-gearing, a driving-shaft with connection to each gearing, the bevel-gears *e* mounted upon the outer-head and connected with the cutter, and the shaft *m'* connected with the feed-gearing and extended through one of the bevel-gears *e*, to drive the cutter in the various positions of the outer-head, substantially as herein set forth.

13. A gear-cutting having a worm-wheel, a worm and change-wheels to control the shifting of the blank, and provided with the bed *a*, the adjustable table *c*, the hinged plate *d* jointed upon the table, the outer-slide and outer-head supported upon the hinged plate, the bearing *g* fixed upon the table and carrying the driving-shaft *e'* in line with the joint of the hinged plate, and a train of gearing connecting the said driving-shaft with the worm, each train embracing the bevel-gears *e'* and the splined shaft *i* extended through one of the said gears to rotate the worm in the different adjusted positions of the table *c*, substantially as herein set forth.

14. A gear-cutting having the bed *a* and column *b*, the mandrel-bearing adjustable thereon, and having an arm projected parallel with the bearing and a bracket adjustable upon the arm to support the end of the mandrel, the hinged plate *d* with outer-slide and outer-head supported thereon, gearing to elevate the hinged plate and an adjustable connection between the outer-slide and the arm to hold the cutter firmly in relation to the blank.

15. A gear-cutting having the bed *a* and column *b*, the mandrel-bearing adjustable upon the column and provided with auxiliary bearing *a'* with arm *c* held adjustably therein, and the bracket adjustable upon the arm to support the mandrel, the hinged plate with outer-slide and outer-head supported thereon, gearing to elevate the hinged plate, and the pivot-link *m* connecting the outer ends of the outer-slide and the arm adjustably, to hold the cutter firmly up to the blank when the outer-slide is inclined.

700,185. LARDING-PIN. HERMANN MUMER, Greifeld, Germany.
Filed Feb. 25, 1901. Serial No. 42,742. (No model.)

Claim.—A larding-pin composed of a pair of pivotally-connected jaws having jaws, and of removable pointed caps adapted to be fitted over said jaws, substantially as specified.

700,186. WHEEL OR RAIL TREAD. BUREAU W. EVANS, New York, N. Y. Filed Dec. 2, 1901. Serial No. 84,447. (No model.)

Claim.—1. The wheel or rail tread comprising a series of part-cylindrical protuberances contiguously arranged and diagonally disposed with respect to the face of the wheel, substantially as described.

2. The wheel or rail tread comprising a series of part-cylindrical protuberances formed upon the periphery of the wheel and integral therewith, the said part-cylindrical protuberances being contiguously arranged and diagonally disposed with respect to the face of the wheel, substantially as described.

3. The wheel or rail tread comprising a series of part-cylindrical protuberances contiguously arranged and diagonally disposed with respect to the face of the wheel, the outer portions of the said protuberances being crossed by milled cuttings perpendicular to the sides of the wheel, substantially as described.

4. The wheel or rail tread comprising a series of part-cylindrical protuberances contiguously arranged and diagonally disposed with respect to the face of the wheel, the outer portions of the said protuberances being milled, substantially as described.

700,187. MAIN VALVE FOR FIRE-EXTINGUISHING SYSTEM. HENRY EVERHART, Cincinnati, Ohio. Filed Nov. 2, 1901. Serial No. 81,922. (No model.)

Claim.—1. A main-valve mechanism for a fire-extinguishing apparatus, consisting of a housing communicating at one end with a water-supply pipe and at the other with a sprinkler-pipe system, a valve contained in this housing and a vent for it in this latter and against which it is normally held by air under pressure contained in the sprinkler-pipe system, that part of the valve-surface exposed to the action of the water and in contact therewith having an independent movement on the valve without affecting the position of this latter and being held in normal position by a yielding pressure.

2. A main valve for fire-extinguishing apparatus to be interposed between an air-charged sprinkler-pipe system and a water-supply pipe therefor and intended to normally prevent such supply, the same being provided with an elastic cushion on that side of it which is in contact with the water and subject to the pressure thereof, such cushion being capable of a movement independent of the valve and without affecting at such time the position thereof.

3. A main valve for fire-extinguishing apparatus to be interposed between an air-charged sprinkler-pipe system and a water-supply pipe therefor and intended to normally prevent such supply, the same having a housing on the water side and a head fitted thereto with an elastic pressure and in a manner to be capable of a movement independent of the valve and without affecting at such time the position thereof.

4. A main valve for fire-extinguishing apparatus to be interposed between an air-charged sprinkler-pipe system and a water-supply pipe therefor and intended to normally prevent such supply, the same having two seating-contacts at 14 and 15, a housing 24 between them and an elastically-supported head 23 therein.

5. Is a valve mechanism for fire-extinguishing apparatus involving an air-charged sprinkler-pipe system and a water-supply pipe therefor, the combination of a valve-housing interposed between the two and in communication with each, two valve-seats therein, a valve for them adapted to have simultaneously seating-contact with both seats and bolts 25 accessible from the outside whereby the position of one of these valve-seats may be adjusted within the valve-housing.

700,188. GAS-PURIFIER GRID. CHARLES R. FARMER, JR., Toledo, Ohio. Filed Aug. 7, 1901. Serial No. 71,175. (No model.)

Claim.—1. A grid for a gas-purifier composed of comparatively wide bars or slats having their edges in the same horizontal plane, overlapping and vertically spaced apart, making horizontal or nearly horizontal gas-passages, substantially as described.

2. A grid for a gas-purifier composed of comparatively wide transversely-inclined bars or slats having their edges in the same horizontal plane, overlapping and vertically spaced apart, and having means at their lower edges for arresting or holding the purifying material at the angle of repose, substantially as described.

3. In a gas-purifier, the combination with inclined supporting-seats and spacing-risers of wide transversely-inclined overlapping bars, or slats, having horizontal gas-passages between them, substantially as described.

4. A bar or slat for a purifier-grid having flat opposite sides and a head or flange perpendicular to its face, at one edge, substantially as described.

5. A bar or slat of a purifier-grid having in its face near one edge a longitudinal depression, and at its edge a head or flange rising above the bottom of said depression, substantially as described.

6. A bar or slat of a purifier-grid having longitudinal beads or flanges projecting from its opposite faces at or near its opposite edges, substantially as described.

7. In a gas-purifier box, the horizontally-placed curved strips having inclined seats and spacing-risers, in combination with the transversely-inclined overlapping bars, or slats, substantially as described.

8. A bar or slat of a purifier-grid having in its face, near one edge, a longitudinal depression, the bottom of which is inclined downward and outward, and a longitudinal head rising above the bottom, substantially as described.

9. In a purifier-box, the grids composed of overlapping bars or slats inclined upward and inward from opposite sides of the box for directing gas from the sides toward the interior of the purifier material, substantially as described.

10. A bar or slat of a purifier-grid longitudinally beveled at the edge of one face and having in its opposite face near the same edge a longitudinal depression, and at its edge in such face a head or flange rising above the bottom of said depression.

700,189. BUFFING-ROLL. ALFRED E. FOWLER, Central Falls, R. I., assignor to United Shoe Machinery Company, Paterson, N. J., a Corporation of New Jersey. Filed Aug. 12, 1901. Serial No. 71,200. (No model.)

Claim.—1. A buffing-roll having, in combination, a core, a covering-pad consisting of a sheet of yielding material wound around the core, and means for removably securing the ends of said sheet to the core, substantially as described.

2. A buffing-roll having, in combination, a core, a covering-pad consisting of a sheet of yielding material substantially rhomboidal in shape wound around the core, and means for removably securing the ends of said sheet to the core, substantially as described.

3. A buffing-roll having, in combination, a core, a covering-pad consisting of a sheet of yielding material substantially rhomboidal in shape provided with thin projecting end strips wound around the core, and clamps engaging said end strips for removably securing said sheet to the core, substantially as described.

4. A covering-pad for a buffing-roll consisting of a sheet of yielding material substantially rhomboidal in shape provided with thin projecting end strips, substantially as described.

5. A covering-pad for a buffing-roll consisting of a sheet of yielding material substantially rhomboidal in shape and a thin backing-sheet projecting beyond the ends of said sheet, substantially as described.

6. A covering-pad for a buffing-roll consisting of a sheet of yielding material substantially rhomboidal in shape adapted to be wound around the core of a buffing-roll and provided at its ends with means whereby it may be removably secured thereto, substantially as described.

7. A buffing-roll having, in combination, a core, a covering of abrasive material, a clamp mounted in the end of the core arranged to clamp the covering of abrasive material, a clamp-extending ring rotatably mounted on the end of the core, and means for locking said ring, substantially as described.

8. A buffing-roll having, in combination, a core, a covering of abrasive material, a clamp mounted in the end of the core arranged to clamp the covering of abrasive material, a clamp-extending ring rotatably mounted on the end of the core, ratchet-teeth on the end of the core and a pawl carried by said ring arranged to engage the ratchet-teeth, substantially as described.

700,190. ART AND PROCESS OF CONVERTING PEAT INTO FUEL. JAMES O. GREEN and HARRY T. MARSH, Whitewater, Wis. Filed Sept. 12, 1901. Serial No. 71,201. (No specimens.)

Claim.—The art or process of converting peat into a compact non-flammable substance for use as fuel by drying, and then simultaneously grinding heating and compressing substantially as herein described.

700,191. MACHINE FOR MAKING GLASS BOTTLES. LEONARD GEORGE, London, England, assignor to Globe Bottle Machine Company, Jersey City, N. J., a Corporation of New Jersey. Filed July 12, 1900. Serial No. 38,518. (No model.)

Claim.—1. The combination, in a machine for making glass bottles, of a vertical pillar; a blasted neck-mold, a blasted parison-mold and means for admitting air supported by said pillar and reversible together on a horizontal axis, the halves of said parison-mold being movable apart and upwardly into another plane after inversion; blasted finishing body-molds the parts of which in succession are movable horizontally on a vertical axis into the positions vacated by those of said parison-mold beneath the common neck-mold, finishing bottom-molds coacting in succession with a body-mold and said neck-mold, and supports for said body-molds and bottom-molds movable horizontally around said pillar and supported thereby.

2. The combination, in a machine for making glass bottles, of a vertical pillar; a blasted neck-mold, a blasted parison-mold, a mouth-forming and air-admitting plunger and a combined plunger-support and conduit, supported by said pillar and reversible together on a horizontal axis, the halves of said parison-mold being movable apart and upwardly into another plane after inversion, blasted finishing-molds the parts of which in succession are movable horizontally on a vertical axis into positions vacated by those of said parison-mold beneath the common neck-mold, finishing bottom-molds coacting in succession with a body-mold and said neck-mold and supports for said body-molds and bottom-molds movable horizontally around said pillar and supported thereby.

3. The combination, in a machine for making glass bottles, of a vertical pillar; a blasted neck-mold a blasted parison-mold and means for

admitting air, supported by said pillar and reversible together on a horizontal axis, the halves of said parison-mold being movable apart and upwardly into another plane after inversion; a pair of finishing body-molds and bottom-molds pivotally supported by said pillar in juxtaposition to the inverted neck-mold and movable horizontally in succession into alignment therewith and into a diametrically opposite delivery position.

4. The combination, in a machine for making glass bottles, of a vertical pillar; a hinged neck-mold, a hinged parison-mold, a mouth-forming and air-admitting plunger and a combined plunger-support and air-conduit supported by said pillar and reversible together on a horizontal axis, the halves of said parison-mold being separable to expose the partly-formed bottle depending from the neck-mold; and adjacent finishing body-molds and bottom-molds supported by said pillar and movable on its vertical axis into successive alignment with the inverted neck-mold, for cooperation therewith in completing successive bottles.

5. The combination, in a machine for making glass bottles, of a head-casting neck-mold composed of parts separable laterally to release the finished bottle, and provided with spring-detents projecting from its end face, and interchangeable parison-molds and finishing body-molds composed of laterally-separable parts engaging with said detents to align themselves in succession with said neck-mold.

6. The combination, in a machine for making glass bottles, of a head-casting neck-mold composed of parts separable laterally and reversible on a horizontal axis, a parison-mold composed of laterally-separable parts and reversible with said neck-mold, a finishing body-mold composed of laterally-separable parts interchangeable with those of said parison-mold, spring-detents retaining the other molds successively in alignment with said neck-mold, and handles by which the resistance of said detents is overcome.

7. The combination, in a machine for making glass bottles, of a horizontal air-tube, a face-plate turning on the axis of said air-tube, a pair of laterally-separable neck-mold parts and a hand-lever carried by said face-plate, a pair of parison-mold parts separable on the axis of said air-tube, a combined plunger-support and air-conduit supported by said air-tube, and a mouth-forming and air-admitting plunger actuated by said hand-lever.

8. The combination, in a machine for making glass bottles, of a head-casting neck-mold reversible to suspend the partly-formed bottle, a plurality of finishing body-molds pivotally supported in their working plane and movable in succession into and out of alignment with the reversed neck-mold, for completing successive bottles, and a vertical pillar supporting the whole and around which said body-molds revolve.

9. The combination, in a machine for making glass bottles, of a head-casting neck-mold composed of parts separable horizontally to release the finished bottle, a plurality of finishing body-molds, open at both ends, movable successively into alignment with said neck-mold and each composed of horizontally-separable parts, a plurality of bottom-molds engaging with the lower ends of said body-molds respectively, and movable horizontally therewith after the blowing is completed, and a supporting-pillar common to said neck-mold, body-molds and bottom-molds, and around which said body-molds and said bottom-molds revolve, substantially as hereinbefore specified.

700,192. AGRICULTURAL UTENSIL. EDUARD H. GUNDEL, Cologne, Germany. Filed Mar. 20, 1901. Serial No. 65,749. (No model.)

Claim.—An agricultural implement for extracting roots without damaging the same, consisting of a pair of arms, pivoted together above the ground and having the ends below the pivot bent inwardly toward each other and a set of straight prongs mounted at each end and having the members of one set engaging between those of the other in the manner and for the purpose substantially as described.

700,193. VEGETABLE-STRAINER. GEORGE H. GUNDEL, Rochester, N. Y. Filed Feb. 22, 1901. Serial No. 65,694. (No model.)

Claim.—1. In a device of the character described, a receptacle having a screen-bottom, a shaft extending through the receptacle above the screen-bottom and adjacent thereto, and a flat plate secured to the shaft, the screen curving by engaging with the plate to prevent the complete rotation thereof, substantially as shown and described.

2. In a device of the character specified, a receptacle having open top and bottom and formed with a band about its bottom, a removable screen-bottom on said band, a shaft mounted transversely of the receptacle and substantially midway between its ends above the screen-bottom and adjacent thereto, a flat plate secured to said shaft, the screen curving to prevent the complete rotation of the plate by engaging the same, and means for actuating said shaft, substantially as shown and described.

700,194. WASHING-MACHINE. EDWARD D. HARRISON, Vancouver, Wash. Filed Feb. 4, 1902. Serial No. 92,989. (No model.)

Claim.—1. In a washing-machine, the combination with a frame and a rotatable oscillating tub supported thereby, of a bar supported by the frame and extending across the tub, hangers detachably engaging the bar and a vertically-adjustable, non-oscillating rubber band to the lower ends of the hangers within the tub.

2. In a washing-machine, the combination with an oscillating tub mounted on hollow trunnions, of a stationary bar extending through the

transverse and across the ends-box, non-oscillating hangers detachably engaging the bar, and a rubber supported by the hangers within the ends-box.

3. In a washing-machine, the combination with an oscillating ends-box having an angular bar across the ends, of a removable, vertically-movable rubber supported in the ends-box by hangers, said hangers having angular slots receiving the bar, whereby oscillation of the rubber is prevented but vertical movement permitted.

700,195. THILL-COUPLINE. MATHEW L. HIGGINS and WILLIAM W. REVELL, PHOTO. & D. Filed Jan. 22, 1902. Serial No. 99,865. (No model.)

Claim.—1. In a thill-coupling, a clip formed with a projecting arm, a spring-actuated angular rocking arm pivoted to the first-mentioned arm, one side of the angular rocking arm engaging the ears upon the clip, the other being bent at right angles to the respective sides parallel with the ears, substantially as shown and described.

2. In a thill-coupling, a clip formed with a plate projecting at one side thereof, an angular rocking arm pivoted to the said plate, a spring secured to the plate, the said spring engaging the said rocking arm, one side of the angular arm engaging the ears upon the clip, the other being bent at right angles to the respective sides of the arm parallel with the ears, substantially as shown and described.

3. In a thill-coupling, a clip having a flat projecting arm, a spring-actuated angular arm pivoted to the said flat arm, one side of the angular arm being bent at right angles to the respective sides, the other resting upon the ears, and of an antirattler formed upon that portion which rests upon the ears, substantially as shown and for the purpose set forth.

700,196. STARCHING-MACHINE. EDWARD B. HENOLD, Anderson, Ind. Filed Aug. 17, 1901. Serial No. 72,400. (No model.)

Claim.—1. In a starching-machine the combination of the starch-pot, a drum mounted therein, having a closed body and longitudinal channels in its periphery extending from end to end, a woven-wire fabric covering the said drum, a fabric on the outside of said wire fabric, a plurality of rollers parallel with the drum and mounted between said drum and the bottom of the pot, and an endless belt mounted on rollers supported on

each side of said drum, said belt passing between the under side of said drum and the series of rollers in the bottom of the pot, substantially as set forth.

2. In a starching-machine the combination of a drum having a closed body to exclude starch from its interior, a woven-wire sleeve surrounding the periphery of the drum and supported out of continuous contact with said periphery by longitudinal ribs or corrugations, and windings of loose pile fabric around said woven-wire sleeve, substantially as set forth.

3. A starch-pot, a drum suspended therein, a plurality of rollers between the drum and the bottom of the pot, independent frames on either side of the pot to support the rollers, said frames consisting of a bent bar for each having shaft-bearings for the shafts of the rollers and eyes at the ends of the bars, eyebolts connected to the ends of the frames, cups through which the eyebolts pass, said cups having springs to support the eyebolts and means for regulating the tension of the springs, said cups being supported by wrist-pins from the sides of the pot and an endless belt passing around the rollers.

4. In a starching-machine, a starch-pot, a drum, a plurality of rollers, an endless belt passing around the rollers and a pair of frames to support the rollers, said frames being elastically supported at their ends whereby they will be drawn with a yielding pressure toward the drum and said frames being hinged to the supports to permit swinging adjustment of the frames in vertical planes and means for adjusting the ends of the frames independently of each other.

5. A starch-pot, a drum, a plurality of rollers, an endless belt passing around the rollers, a pair of frames to support the rollers consisting of bent bars having indentations on their inside edges to form bearings for the roller-shafts, eyebolts pivotally secured to the ends of the frames, said bolts being screw-threaded, cups supported by horizontal pivots the eyebolts passing through the cups, nuts on the projecting threaded ends of the eyebolts and springs between the nuts and the bottoms of the cups around said eyebolts.

6. In a starching-machine, a drum having a closed body to exclude starch from its interior, a corrugated sleeve removably secured to the periphery of the drum, a woven-wire sleeve surrounding and removably secured to the corrugated sleeve and windings of a loose-pile fabric around the woven-wire sleeve.

7. In a starching-machine, a starch-pot, a drum adjustable vertically, rollers parallel with the drum between the drum and the bottom of the pot and adjustable to and from the drum said rollers being below the axis of the drum, a roller above the axis of the drum at the front of the machine and adjustable in a plane oblique to the horizontal, a second roller above the axis of the drum on the opposite side of the latter from the obliquely-adjustable roller and adjustable horizontally, and a belt passing around all of the rollers.

8. In a starching-machine, a starch-pot, a drum, rollers below the axis of the drum and parallel therewith said adjustable to and from the drum, a roller above the axis of the drum and adjustable in an oblique plane, a roller on the opposite side of the drum from the obliquely-adjustable roller said last roller adjustable in a horizontal plane and being above the axis of the drum, a third roller outside of and parallel with the second and horizontally-adjustable roller and a belt passing around all of the rollers and between the rollers and the drum.

700,197. TURN-CUTTER. WALTER HENRY, Chicago, Ill. Filed Apr. 22, 1901. Serial No. 64,966. (No model.)

Claim.—1. A device of the character described, comprising a rotatable spindle carrying a cutter, a concentric bearing at one end of the spindle, an eccentric bearing at the opposite end, and means for limiting the rotation of the spindle.

2. A device of the character described, comprising a rotatable spindle carrying a cutter, a concentric bearing at one end of the spindle, an eccentric bearing at the opposite end thereof, means for limiting the re-

tion of the spindle, and means for controlling the distance of its insertion into a tube.

2. A device of the character described, comprising a rotatable spindle having a reduced inner end and an outer polygonal end, an intermediate outer, a circular rotatable bearing mounted concentrically upon the reduced end of the spindle, a circular bearing mounted concentrically upon the outer portion of the spindle and carrying a step projection, and a step device fitted to the polygonal end of the spindle and located in the path of the step projection.

4. A device of the character described, comprising a rotatable spindle having an outer polygonal end, an intermediate outer, a rotatable bearing mounted upon the spindle between the outer and the polygonal end thereof, and carrying a step projection, and a step device carried by the polygonal end of the spindle and arranged in the path of the step projection whereby to limit the rotation of the spindle.

5. A device of the character described, comprising a rotatable spindle having an outer polygonal end, an intermediate outer, a rotatable bearing mounted upon the spindle between the outer and the polygonal end thereof, and having a step projection, and a step device having a polygonal opening fitting the outer end of the spindle and provided with means for rigidly securing it to the said end.

6. A device of the character described, comprising a rotatable spindle, having a lateral outer, a bearing rotatably mounted upon the spindle at the outer side of the outer, and an arm connected to the bearing, and having a lateral projection adapted to enter an adjacent line and thereby hold the arm and bearing against rotation.

7. A device of the character described, comprising a rotatable spindle, having a lateral outer, a bearing rotatably mounted upon the spindle at the outer side of the outer, and provided with a polygonal portion, and a holding-arm, having a wrench-head adapted for detachable engagement with the polygonal portion of the bearing, and also provided with a lateral projection to enter a line and hold the arm and bearing against rotation.

8. A device of the character described, comprising a rotatable spindle, having a lateral outer, a bearing rotatably mounted upon the spindle at the outer side of the outer, and provided with a polygonal portion, and an arm disposed at substantially right angles to the spindle, and having a terminal wrench-head for detachable engagement with the polygonal portion of the bearing, and an opposite terminal lateral projection, which is adjustable longitudinally upon the arm.

9. A device of the character described, comprising a rotatable spindle, having a lateral outer, a bearing rotatably mounted upon the spindle at the outer side of the outer, and provided with a polygonal portion, and a holder-arm, having a terminal wrench-head for detachable engagement with the polygonal portion of the bearing, the opposite end of the arm having a longitudinal slot, and a lateral projection adjustable longitudinally in the slot.

10. A device of the character described, comprising a rotatable spindle, having a polygonal outer end, an intermediate circular enlargement or collar, having a marginal recess, a collar mounted in the recess and projected outwardly beyond the margin of the collar, a circular rotatable bearing mounted concentrically upon the inner end of the spindle, a sleeve-bearing mounted concentrically upon the spindle between the collar and the polygonal portion of the spindle, the inner end portion of the sleeve being cylindrical in shape and of substantially equal diameter with the inner bearing, the outer end portion of the sleeve being polygonal in shape, and having an outer terminal longitudinal step projection, there being an intermediate outwardly-directed marginal flange between the cylindrical and polygonal portions of the bearing-sleeve, a step-collar removably fitted to the polygonal end of the spindle, and provided with a marginal step projection lying in the path of the step projection of the bearing-sleeve, and also having a set-screw to engage the spindle, the polygonal end of the spindle projecting beyond the collar for the reception of an operating device, in combination with a holder-arm for the sleeve-bearing, consisting of an arm having a terminal bifurcation or wrench-head adapted for detachable engagement with the polygonal portion of the bearing-sleeve, and having an opposite terminal lateral projection extending toward the inner end of the spindle and adapted to be entered into a line to hold the arm and bearing against rotation.

11. A device of the character described, comprising a rotatable spindle, having an intermediate lateral outer an inner terminal concentric bearing, and an outer concentric bearing, both bearings being of substantially the same diameter, and having correspondingly-inclined bearing-openings for the reception of the spindle, whereby the latter is inclined across the longitudinal axis of a tube when in operative position.

700,198. FURNACE FOR BURNING FINE FUEL. RICHARD REINHOLD, Berlin, Germany. Filed Oct. 23, 1901. Serial No. 73,303. (No model.)

Claim.—1. A furnace for burning fine fuel comprising a combustion-chamber having a feed-opening at the top, and pipes crossing the combustion-chamber at different levels below the feed-opening, and also insulating the combustion-chamber and the pipes which cross it.

2. A furnace for burning fine fuel comprising a combustion-chamber having a contracted upper end, a grate placed in a contracted chamber below the combustion-chamber, a feed-hopper for feeding fine fuel into the upper end of the combustion-chamber, and water-pipes for the circulation of water in the combustion-chamber which cross the combustion-chamber at different levels and which also insulate the crossing pipes and are contracted in area at the upper end of the combustion-chamber.

3. A furnace for burning fine fuel comprising a combustion-chamber having a feed-opening at the top, a grate at the bottom of the combustion-chamber, water-pipes crossing the combustion-chamber at different levels directly below the feed-opening and in different vertical planes in the combustion-chamber, and water-pipes surrounding the crossing pipes which extend from top to bottom of the combustion-chamber.

700,199. DEVICE FOR SEALING ENVELOPES. ALFRED REYNOLDS, Brooklyn, N. Y., assignor of three-fifths to Alexander McIntosh and Ernest Radloff, New York, N. Y. Filed Jan. 12, 1903. Serial No. 24,512. (No model.)

Claim.—1. In an envelop-sealing machine, a sealing device, a maintaining device, and operating mechanism for the sealing device acting to first take and temporarily detain the envelop and then seal the same, as set forth.

2. In an envelop-sealing machine, a sealing device, a maintaining device, means for delivering an envelop to the sealing device, and mechanism for operating the sealing device, the operation of the said mechanism being so timed relatively to the delivery means that the envelop will be

temporarily held by the sealing device prior to the sealing of the same, as set forth.

3. In an envelop-sealing machine, a sealing device, a moistening device, an envelop-holder, the said holder and sealing device being movable relatively toward and from each other, and means whereby when the holder and sealing device are moved toward each other an envelop will be delivered to the sealing device and held thereby until the said parts have moved away from each other and again start to move toward each other when the envelop will be sealed, as set forth.

4. In an envelop-sealing machine, sealing-rollers, means for feeding an envelop to the said rollers, means for moistening the envelop before it is sealed by the rollers, and mechanism for operating the rollers to cause them to draw an envelop between them, the operation of each mechanism being so timed relatively to the feeding means that the envelop will be detained between the rollers after it has been moistened thereby and before it is discharged therefrom, as set forth.

5. In an envelop-sealing machine, sealing-rollers, means for holding the envelop, said envelop-holding means and the sealing-rollers being movable relatively toward and from each other, and means for turning the sealing-rollers during the movement of the parts toward each other, whereby the said rollers will be operated to discharge the envelop at each time, said rollers being stationary during the movement of the rollers and the envelop-holding means apart, whereby the envelop when caught by the rollers will be temporarily detained during the movement of the envelop-holder and rollers away from each other, as set forth.

6. In an envelop-sealing machine, sealing-rollers, an envelop-holder, the holder and sealing-rollers being movable relatively toward and from each other, means for turning the sealing-rollers during the movement of the parts toward each other, said rollers being stationary during the movement of the holder and sealing-rollers apart, and a moistening device carried by one of the said parts for applying moisture to the envelop prior to its entrance between the said rollers, substantially as described.

7. In an envelop-sealing machine, sealing-rollers, a carrier for the envelopes movable toward and from the sealing-rollers, means for operating the sealing-rollers as the carrier moves toward the said rollers, the said rollers being stationary during the movement of the carrier away from the rollers, and a moistening device carried by the carrier for applying moisture to the envelop prior to its entrance between the sealing-rollers, substantially as described.

8. In an envelop-sealing machine, sealing-rollers, an envelop-carrier movable toward and from the sealing-rollers, means for operating the sealing-rollers as the carrier moves toward said rollers, the rollers being stationary during the movement of the carrier away from the sealing-rollers, and a moistening-roller yieldingly mounted under the carrier at its front edge, substantially as described.

9. In an envelop-sealing machine, sealing-rollers, a platen in front of and adjacent to the lower sealing-roller, an envelop-carrier movable toward and from the said rollers, a moistening device carried by the carrier and coacting with the platen to moisten the envelop, and means for operating the sealing-rollers and carrier, substantially as described.

10. In an envelop-sealing machine, sealing-rollers, a platen in front of and adjacent to the lower sealing-roller, an envelop-carrier slidable toward and from the rollers, a pivoted moistening device carried by the carrier and coacting with the platen to moisten the envelop, and means for operating the sealing-rollers from the carrier, substantially as described.

11. In an envelop-sealing machine, sealing means, a moistening-pad in front of and below the sealing means, a carrier slidable toward and from the sealing means, a moistening-roller carried by the carrier, and means for bringing said pad and roller into contact on the outward movement of the carrier, substantially as described.

12. In an envelop-sealing machine, sealing means, a moistening-pad in front of and below the sealing means, an envelop-carrier slidable toward and from the sealing means, a moistening-roller pivotally mounted on the under side of the carrier, means for holding the roller close to the under side of the carrier in the delivery movement of said carrier and releasing the same to allow it contact with the moistening-pad at the end of said delivery movement, and means for returning the roller to its normal position on the return movement of the carrier, substantially as described.

13. In an envelop-sealing machine, sealing-rollers, a moistening-pad below and in front of the said rollers, an envelop-carrier slidable toward and from the sealing-rollers, a moistening-roller yieldingly mounted in a support pivoted to the under side of the carrier, device for holding the roller close to the under side of the carrier in the delivery movement of the same, and releasing the same to allow the roller to contact with the moistening-pad at the end of the said delivery movement of the carrier, and means for returning the roller-support to its normal position on the return movement of the carrier, substantially as described.

14. In an envelop-sealing machine, the combination with sealing-rollers, an envelop-holder, the sealing-rollers and holder being movable

relatively toward and from each other, a ratchet-wheel fixed to the shaft of one of the sealing-rollers, a pinion loose on the shaft of the said sealing-roller and carrying a pawl engaging the ratchet-wheel, and a rack by means of which the said loose pinion is driven whereby the feed-rollers will be driven when the parts are moved toward each other and remain stationary when said parts are moved apart, as and for the purpose set forth.

15. In an envelop-sealing machine, the combination of sealing-rollers, a ratchet-wheel fixed to the shaft of one sealing-roller, a pinion loose on the shaft of said roller and carrying a pawl engaging the ratchet-wheel, an envelop-carrier movable toward and from the feed-rollers, and a rack carried by the carrier and meshing with the said pinion, substantially as and for the purpose set forth.

16. In an envelop-sealing machine, a pair of sealing-rollers, a ratchet-wheel fixed to the shaft of one of said rollers, a pinion loose on the shaft of the said roller and carrying a pawl engaging the ratchet-wheel, a second pair of sealing-rollers in rear of the first pair, a pinion fixed to the shaft of one of the second pair of rollers, an envelop-carrier movable toward and from the feed-rollers, and a rack carried by the carrier and meshing with the pinions of the said rollers, substantially as described.

17. In an envelop-sealing machine, the combination of sealing-rollers, a moistening device, an envelop-holder, said holder and sealing-rollers being movable relatively toward and from each other, and an adjustable gage on the holder, whereby the holder is adapted for various sizes of envelopes and provides means for holding an envelop thereon with its edge projecting beyond the edge of the holder to facilitate its entrance between the rollers, substantially as described.

18. A pair of sealing-rollers, a table mounted to reciprocate to and from said sealing-rollers, an actuating mechanism common to both the table and the rollers, and a moistening-roller carried by the table and having movement to and from the table in a vertical direction.

19. A pair of sealing-rollers, a table having reciprocating movement to and from the space between the sealing-rollers, a moistening-roller located beneath the table, and having pivotal connection therewith, the moistening-roller being normally held close to the under side of the table, and a trip device for the said moistening-roller, as described.

20. In a sealing device for envelopes, pairs of sealing-rollers, tension devices for the said rollers, actuating devices for said rollers and a movable table connected with said actuating devices, a tank adapted to contain liquid, a moistening device located within said tank and extending out therefrom, a moistening-roller pivoted beneath said table, adapted to travel with the table to the sealing-rollers and having movement downward in direction of the moistening device, the moistening-roller being normally close to the under side of the table, and a trip mechanism for the moistening-roller, substantially as described.

21. In a machine for sealing envelopes, a pair of sealing-rollers, one being located above the other, means imparting movement to the sealing-rollers, a table connected with the said rollers, adapted to carry an envelop, a frame pivotally mounted beneath the said table, a moistening-roller carried by the said frame, means for raising and lowering the moistening-roller, a tank located beneath the sealing-rollers, and an absorbent material located within said tank and extending therefrom, which absorbent material is adapted to be engaged by the moistening-roller at its downward movement, as specified.

22. In a machine for sealing envelopes, a duplicate pair of sealing-rollers, a table adapted to carry an envelop, having movement to and from the sealing-rollers, an actuating mechanism for the table and the sealing-rollers, a spring-controlled frame pivoted to the table, a locking and trip mechanism for the said frame, a moistening-roller carried by the frame, and a moistening device adapted to be engaged by the moistening-roller on its downward movement, said moistening-roller having a movement with the table toward the sealing-rollers and a downward movement to the moistening device together with an upward movement to the said table, as set forth.

700,200. TONGUE-REGULATING TOOL. FRANKLIN BOVIER, Detroit, Mich. Filed May 6, 1901. Serial No. 68,994 (No model.)

Claim.—1. In a tongue-regulating tool, the combination with a stationary jaw, of complementary handle-sections at one side of said jaw, the latter being carried by one of the sections, an outer movable jaw upon the opposite side of and spaced from the stationary jaw, an operative connection between said movable jaw and the other handle-section, and a plurality of inwardly-extending pointed projections carried by the movable jaw.

2. In a tongue-regulating tool, the combination with a stationary jaw, of complementary handle-sections at one side of the jaw and extending downwardly in angular relation thereto, a connection between said jaw and one of the handle-sections, a movable jaw upon the opposite side of and spaced from the stationary jaw, an operative connection between said

movable jaw and the complementary handle-section, and a plurality of inwardly-extending pointed projections carried by the movable jaw.

2. Is a tool-regulating tool, the combination with the pivoted handle-section, of a tubular head carried by one of said sections, an inner stationary jaw mounted upon and fixedly secured to the head, an outer movable jaw carrying a plurality of inwardly-extending pointed projections and provided with a shank extending through and adapted to be reciprocated within the tubular head, and a connection between the inner shank end and the other handle-section.

4. Is a tool-regulating tool, the combination with an arched handle-section terminating at its outer end in a forwardly-projecting tubular head, of a complementary handle-section pivoted to the arched section, a stationary jaw adjustably secured upon the head, a shank extending through and beyond the tubular head carrying a jaw at its outer end, a plurality of pointed projections extending inward from the jaw on the shank, a connection between the inner shank end and the complementary handle-section, and a spring upon the shank acting normally to spread the jaws.

5. Is a tool-regulating tool, the combination with a stationary jaw, of complementary handle-sections at one side of said jaw, the latter being carried by one of the sections, an outer movable jaw upon the opposite side of, and mounted for reciprocation in substantially parallel alignment with, said stationary jaw, an operative connection between the movable jaw and the complementary handle-section, and inwardly-extending pointed projections carried by the said movable jaw.

700,201. ANTI-FRICTION ROLLER-BEARING. HERMAN HOFF, New York, N. Y., assignor of one-half to Fred F. Harris, New York, N. Y. Filed July 17, 1901. Serial No. 68,097. (No model.)

Claim.—In a roller-bearing, the combination with a journal-box having a pair of circular flanges thereon, of a pair of carrier-rings having a series of semicircular notches in their peripheries, rollers each provided with a spindle and a disk on each end, said spindles being journaled in said notches and located to run on said circular flanges as raceways to keep the rollers clear from contact with the box, and a shaft extending through said rings and bearing wholly on said rollers, substantially as described.

700,202. MECHANICAL MOVEMENT. FREDERICK W. JAMES, New York, N. Y. Filed July 11, 1901. Serial No. 67,882. (No model.)

Claim.—1. A mechanical movement comprising a rotary shaft having a plurality of projecting arms mounted upon the same and positioned at different distances from the shaft; said projecting arms being mounted to turn with the shaft and to have a movement at an angle to the plane of their rotation, and end abutments adapted to conform to the arms, substantially as described.

2. A mechanical movement comprising a rotary shaft having a plurality of independent projecting arms mounted upon the same and positioned at different distances from the shaft; said projecting arms being mounted to turn with the shaft and to have a movement at an angle to

the plane of their rotation, and end abutments adapted to conform to the arms, substantially as described.

700,203. GANG-EDGER. CHARLES JOHNSON, Minneapolis, Minn., assignor of one-half to Arthur R. Rogers, Minneapolis, Minn. Filed Nov. 5, 1901. Serial No. 61,174. (No model.)

Claim.—1. The combination with means for feeding the boards, of a spindle formed by two shaft-sections which telescope one into the other and are connected for common rotation, independent bearings for said two shaft-sections, a saw carried by each shaft-section, and means for adjusting one of said shaft-sections with respect to the other to vary the saws.

2. In a gang-edger, the combination with means for feeding the boards, of a telescopically-adjustable rotary spindle, one section of which is fixed against endwise movement, a saw carried by each spindle-section, and an adjustable bearing-head in which said adjustable spindle-section is mounted, means for adjusting the bearing-head, and means for driving said spindle, substantially as described.

3. In a gang-edger, the combination with means for feeding the boards, of a telescopically-adjustable rotary spindle, the sections of which have sliding spline-and-follower engagement and one section of which is fixed against adjustment, a saw carried by each spindle-section, a pulley on the adjustable spindle-section, an adjustable bearing-head in which said adjustable spindle-section is mounted, and a screw for adjusting the said head, substantially as described.

700,204. BOLT-LOCK. OLIVER JOSE, Kansas City, Kans. Filed Apr. 13, 1901. Serial No. 66,483. (No model.)

Claim.—The combination with a car-truck, embodying vertical angular-headed bolts 10, a plate 5 through which said bolts extend and interposed between said heads and the top of the truck, plates underlying the truck and provided with threaded holes receiving the threaded ends of said bolts, vertical bolts at opposite sides of the truck extending through said plate and having angular heads resting upon said plate, and threaded ends engaging the underlying plates, a plate 11, upon the first-named plate and provided with openings snugly fitting the heads of the truck-bolts and engaging the heads of the other bolts to prevent them from

turning, slotted pins extending up through the first-named plate and plate 11, and having their heads underlying the first-named plate, and wedge-shaped cutters or keys engaging said slots and the upper side of said plate 11, to clamp said plate tightly down upon the first-named plate, substantially as described.

700,205. GAS-BURNER. PETER KELLER and PHILIPP SCHLIER, Chicago, Ill., assigners, by direct and mesne assignments, to said Keller and Lisa Entemann, Chicago, Ill. Filed Feb. 19, 1901. Removed Apr. 17, 1902. Serial No. 168,423. (No model.)

Claim.—A device for regulating the flow of gas comprising a base provided with an upwardly-extending nipple, an exterior groove in said nipple adjacent its lower end, a central opening in said base and through said nipple, a fluted cylindrical cap adapted to fit loosely over said nipple, prongs on the lower end of said cap extending into said groove, a casing adapted to be mounted on said base and over said cap, and a central opening in the upper wall of said casing of less diameter than said cap, the latter being adapted to be raised by successive pressure of gas and strike the upper wall of said casing, thereby partially closing said central opening and decreasing the flow of gas therethrough, said cap by reason of its corrugations preventing the flow of gas from being entirely shut off at any time, substantially as described.

700,206. AUXILIARY REVERSING-GEAR FOR MACHINE-TOOLS. HERMANN E. A. KIEHNHARDT, Chemnitz, Germany. Filed Dec. 27, 1901. Serial No. 97,482. (No model.)

Claim.—1. In a device of the class described, the combination with the slide and the driving-shaft operatively connected thereto with means for driving said shaft in either direction, of a fly-wheel mounted to rotate independently of said shaft, means for rotating said fly-wheel in a direction reverse to the forward motion of the shaft, and means for connecting said fly-wheel to the shaft when reversing the movement of the same.

2. The combination with the slide and driving-shaft operatively connected therewith, with means for rotating it in either direction, of a fly-wheel loosely journaled on said shaft and means for automatically coupling and uncoupling said fly-wheel to and from said shaft near the extremities of the movement of the slide.

3. The combination with the slide and driving-shaft operatively connected therewith with means for driving it in either direction, of a fly-wheel journaled on said shaft with means for driving it, clutch mechanism for connecting said fly-wheel to and disconnecting it from the shaft, a movable bar extending into proximity to the slide, stops or abutments on the slide for moving the bar as the slide approaches either extremity of its movement, and means whereby the movement of the bar operates the clutch mechanism.

4. The combination with the slide and driving-shaft operatively connected thereto with means for driving it in either direction, of a fly-wheel loose on said shaft, means for driving the same, a clutch for connecting said wheel to and disconnecting it from the shaft, a movable bar extending into proximity to the slide, abutments on the slide for engaging the bar as the slide approaches either extremity of its stroke, and yielding connections between said bar and clutch whereby the movement of the bar operates the clutch without shock.

700,207. COMBINED RHEOSTAT AND HEATER. MAX G. KIMMEL, Chicago, Ill., assigner, by mesne assignments, of one-half to Heubner Manufacturing Company, Chicago, Ill., a Corporation of Illinois. Filed Oct. 4, 1901. Serial No. 77,593. (No model.)

Claim.—1. In a combined electric rheostat and heater, a stick or rod of resistance material having openings therethrough at various intervals, non-corrusive contacts, and means passing through said openings for securing said contacts to said rod, as and for the purpose set forth.

2. In a combined electric rheostat and heater, a non-metallic stick or rod forming the resistance material, non-corrusive contacts, and pins or studs passing through said stick or rod for clamping said contacts thereto, as and for the purpose set forth.

3. In an apparatus of the class described, an insulating-plate, a resistance stick or rod mounted thereon, a series of contact-points, a series of non-corrusive contacts applied to said stick or rod and each in electrical connection with the contact-point, and a contact arm or lever operating over said contact-points, as and for the purpose set forth.

4. In an apparatus of the class described, an electric circuit including a pivoted contact-arm or lever, a resistance stick or rod, a series of non-corrusive contacts in electrical connection therewith, said contact arm or lever operating over said contact-points, whereby the resistance of said arm may be varied, as and for the purpose set forth.

5. In an apparatus of the class described, an electric circuit including a pivoted contact arm or lever, a resistance stick or rod, a series of contact-points in independent electrical connection therewith, said contact arm or lever operating over said contact-points, and an automatic retaining device or detent operating to engage and lock said arm or lever, as and for the purpose set forth.

6. In an apparatus of the class described, a resistance stick or rod, an opening formed therethrough, a pin or stud arranged to pass through said opening and provided at one end with a head and having its other end threaded, a nut mounted upon said threaded end and operating to clamp said pin or stud to said resistance-stick, and a contact-point in electrical connection with said pin or stud, as and for the purpose set forth.

7. In an apparatus of the class described, a non-metallic resistance stick or rod having an opening therethrough, a pin or stud passing through said opening and provided with a head at one end and threaded at the other end, a nut mounted upon said threaded end, and non-corrusive contact washers or plates interposed between said head and nut and said stick or rod, and a contact-point in electrical connection with said pin or stud, as and for the purpose set forth.

700,208. WIRE CLOTHES-PIN. LAUREL LAFR and WHITEHEAD TRENKLE, Pittsburg, N. H. Filed Nov. 14, 1901. Serial No. 98,464. (No model.)

Claim.—A wire clothes-pin consisting of two arms *b* connected by an integral vertical spring *a*, the arm *b* being provided with the horizontal spring *c* and the upturned vertical hook *b'*; and the arm *c* being provided with the horizontal and loop *d* to couple with the hook *b'* substantially as and for the purpose set forth.

700,209. MOTOR DRIVING APPARATUS FOR CYCLES. HENRY J. LAWSON, London, England, assignor to Charles R. Flint, trustee, New York, N. Y. Filed Jan. 31, 1906. Serial No. 2,481. (No model.)

Claim.—1. In a motor driving apparatus the combination with a driving-wheel, of a hollow axle or hub therefor, fixed exterior bearings carrying the hub, means for securing said bearings to a rigid frame, a motor mounted on one side of the driving-wheel, a driving-shaft projecting from the motor into the hub of the driving-wheel, but not supporting the vehicle, a bearing within said hub for one end of the motor-shaft, a fixed bearing for the other end of the shaft, means for securing the fixed bearing to a rigid frame, and speed-gear interposed between the motor-shaft and hub of the driving-wheel.

2. In a motor driving apparatus, the combination with a driving-wheel, of a hollow axle or hub therefor, fixed exterior bearings carrying the hub, means for securing said bearings to a rigid frame whereby the vehicle is supported directly on the hub, a motor mounted on one side of the driving-wheel, a driving-shaft free from the weight of the vehicle projecting from the motor through the hub of the driving-wheel and having bearings therein, a fly-wheel mounted on that end of the shaft remote from the motor, fixed bearings at each end of the shaft, means for securing these bearings to a rigid frame, and speed-gear interposed between the shaft and the hub of the driving-wheel at a point intermediate of the bearings for the hub, substantially as set forth.

3. In a motor driving apparatus the combination with a driving-wheel of a hollow axle or hub therefor, fixed bearings carrying the hub, means for securing said bearings to a rigid frame, a motor mounted on each side of the driving-wheel, a driving-shaft projecting from each motor into the hub of the driving-wheel, bearings within said hub for one end of each motor-shaft, fixed bearings for the other end of each shaft, means for securing these last bearings to a rigid frame, and speed-gear interposed between each shaft and the hub of the driving-wheel at points intermediate of the bearings for the hub, substantially as set forth.

4. In a motor driving apparatus, the combination with a driving-wheel of a hollow axle or hub therefor, a motor mounted on each side of

the driving-wheel, a driving-shaft projecting from each motor into the hub of the said driving-wheel, bearings within the hub for one end of each motor-shaft, fixed bearings for the other end of each shaft, means for securing these bearings to a rigid frame, a pinion mounted flat on each driving-shaft, projections on the ends of the hub proper of the driving-wheel, extensions to the hub, projections on these extensions, means for connecting the extensions and hub, spur-wheel mounted between the hub and extensions carried by the projections on each and gearing with the pinions on the driving-shaft, fixed bearings for the extensions, means for securing these bearings to a rigid frame, internally-toothed wheels free to revolve on portions of the rigid frame and engaging the spur-wheels of the motor, and brake-bands whereby the internally-toothed wheels may be controlled, substantially as set forth.

5. In a motor driving apparatus the combination with a driving-wheel of a hollow axle or hub therefor, a motor mounted on one side of the driving-wheel, a driving-shaft projecting from the motor into the hub of the said driving-wheel, a bearing within the hub for one end of the motor-shaft, a fixed bearing for the other end of the shaft, means for securing said fixed bearing to a rigid frame, a pinion flat on the motor-shaft, a projection on one end of the hub proper, an extension to the hub, a projection on this extension, means for connecting the extension and hub, a spur-wheel mounted between the hub and extension carried by the projections on each and gearing with the pinions on the driving-shaft, a fixed bearing for this extension, a fixed bearing for that end of the hub remote from this extension, means for securing both bearings to a rigid frame, an internally-toothed wheel free to turn on a portion of the rigid frame outside the fork and engaging the spur-wheel of the motor-shaft and a brake-band whereby the internally-toothed wheel may be controlled, substantially as set forth.

6. In a motor driving apparatus the combination with a driving-wheel of a hollow axle or hub therefor, a motor mounted on one side of the driving-wheel, a driving-shaft projecting from the motor through the hub of the road-wheel, bearings for the same, a fly-wheel mounted on that end of the shaft remote from the motor, a pinion flat on the motor-shaft outside the hub a projection on one end of the hub proper, an extension to the hub, a projection on this extension, means for connecting the extension and hub a spur-wheel mounted between the hub and extension carried by the projections on each and gearing with the pinions on the driving-shaft, a fixed bearing for this extension a fixed bearing for that end of the hub remote from this extension, means for securing these bearings to a rigid frame, an internally-toothed wheel free to turn on a portion of the rigid frame and engaging the spur-wheel of the motor-shaft and a brake-band whereby the internally-toothed wheel may be controlled, substantially as described.

7. In a motor driving apparatus the combination with a driving-wheel of a hollow axle or hub therefor, fixed bearings for the hub, means for securing said bearings to a rigid frame, a motor mounted on one side of the driving-wheel, a driving-shaft projecting from the motor through the hub of the driving-wheel, and removable longitudinally therefrom, an extension on one side of the hub of the driving-wheel which projects through the hub-bearing on that side, a bearing within the hub for one end of the driving-shaft, a fixed bearing at the other end of the driving-shaft, means for securing this last bearing to a rigid frame, a pinion mounted detachably on that end of the driving-shaft remote from the motor, and speed-gear interposed between the said pinion and the hub extension, substantially as set forth.

8. In a motor driving apparatus, the combination with a driving-wheel of a hollow axle or hub therefor, fixed bearings for the hub, means for securing said bearings to a rigid frame, a motor mounted on one side of the driving-wheel, a driving-shaft projecting from the motor through the hub of the driving-wheel, an extension on one side of the hub of the driving-wheel which projects through the bearing on that side, a bearing within the hub for one end of the driving-shaft, a fixed bearing at the other end of the driving-shaft, means for securing this last bearing to a rigid frame, a fly-wheel and pinion mounted detachably on that end of the driving-shaft remote from the motor, so that the motor thereby becomes detachable, and speed-gear interposed between the said pinion and the hub extension, substantially as set forth.

700,910. STORAGE BATTERY. LEVI W. LOWMEYER, Boston, Mass., assignor to Jowett Storage Battery Company, Pittsfield, Mass., a Corporation of Maine. Filed Feb. 11, 1906. Serial No. 62,545. (No model.)

Claim.—The improved element for storage batteries comprising a number of thin sheets or strips of metal assembled together and composed alternately of oxidizable and unoxidizable, or difficultly-oxidizable sheets or strips all in contact with one another, the said oxidizable strips being adapted to be converted into active material by chemical or electrolytic treatment, and the strips of unoxidizable or difficultly-oxidizable

metal holding between them the layers of native material and thereby supporting the same, substantially as described.

700,211. DOOR-HANGER. WILLIAM LOUGHEE, Fairfield, Iowa. Filed Sept. 12, 1900. Serial No. 29,002. (No model.)

Claim.—1. The combination of a track arranged to have its outer side, its upper and lower edges and the upper and lower portions of its inner side free for the passage of a hanger therealong, a frame having a grooved wheel journaled in its upper end, a guiding device in its lower end adapted to pass below and behind the lower portion of the track, and a pivotal connection for a door below the track, said pivotal connection being located with respect to the guide in a different vertical plane but in substantially the same horizontal plane with the lower part of said guide.

2. The combination of a track of the character described, a hanger-frame having a grooved wheel journaled in its upper end, a guiding device in the central portion of its lower end adapted to pass below and behind the lower portion of the track, and a pivotal connection for a door on each side of said guide, the same being located on substantially the same horizontal plane as the lower part of said guide.

3. The combination of a track of the character described, a hanger-frame having a grooved wheel journaled in its upper end, a guiding device in the central part of its lower end adapted to pass below and behind the lower portion of the track, and pivotal connections for a door on each side of said guide, said pivots being set outside of the vertical plane of the periphery of said wheel.

4. The combination of a track of the character described, a hanger-frame having a grooved wheel journaled in its upper end, a loop in the lower end of the frame below the track and a clevis-shaped strap adapted to hang loosely in said loop and embrace the opposite sides of a door.

5. The combination of a track of the character described, a hanger-frame having a grooved wheel journaled in its upper end, a guiding device in the central portion of its lower end adapted to pass below and behind the lower portion of the track, a loop in the lower end of the frame below the track on each side of the guide, and clevis-shaped straps adapted to hang in said loops and embrace opposite sides of a door.

6. The combination of a track of the character described, a hanger-frame having a horizontally-disposed top part carrying a wheel and two vertically-set side parts connected therewith, said side parts extending below the track and terminating in loops, and having a horizontally-disposed brace connecting them together below the track, a guiding device on the upper edge of said brace between the side parts and adapted to pass below and behind the lower portion of the track, and means for pivotally connecting said loops to a door.

700,212. FULLEY. WILLIAM LOUGHEE, Fairfield, Iowa. Filed Apr. 20, 1901. Serial No. 52,103. (No model.)

Claim.—1. A pulley-frame consisting of adjoining sides having their upper ends approximately horizontal and securely joined together, each side having a central vertical rib and two vertically-disposed side ribs having their outer edges outwardly rounded in horizontal section, and their

lower ends merged into a circular-shaped horizontally-disposed rib or plate intersecting the middle portion of the central rib, the merged plate and ribs being downwardly and outwardly curved to form guards, and then inwardly contracted and joined to the lower end of the central rib, substantially as described.

2. The combination of a pulley-frame, an annular iron thimble fixed in said frame, and a sheave having a hole in its hub with shifted or hardened flues, and adapted to run on said thimble, substantially as described.

3. The combination of a pulley-frame having recesses in the inner faces of its lower ends, a tapering thimble having a short section of its large end cut down to the same size as the small end, and both ends being adapted to fit in said recesses, and a wheel with a tapering hole in its hub adapted to run on said tapering thimble, substantially as described.

4. The combination of a pulley-frame having recesses in the inner faces of its lower ends, a tapering thimble having a short section of its large end cut down to the same size as the small end, and both ends being adapted to fit in said recesses, a wheel with a tapering hole in its hub adapted to run on said tapering thimble, and a bolt passing through said frame and thimble, substantially as described.

5. In a hoisting-pulley, a cast-iron swivel-eye having a tubular neck, and a flange on said neck to hold it in position in the pulley-frame, substantially as described.

6. In a hoisting-pulley, a cast-iron swivel-eye having a tubular neck and upper and lower flanges on said neck, the main part of said eye consisting of a body joined to the upper end of the neck and a web encircling said body and joined to the upper flange and to the sides of the neck above it, substantially as described.

7. The combination of a cast-iron swivel-eye having a tubular neck and upper and lower flanges on said neck, a two-part pulley-frame adapted to fit and turn on said neck between said flanges, and a sheave journaled in the lower part of said frame, substantially as described.

8. In hoisting-pulley, a sheave having a groove for a rope, the sides of which groove are set at an angle to each other, the bottom of the groove being filled out to form the segment of a circle and the edges of the groove being rounded off on the segment of a circle, said circle being of a size with respect to the size of the groove to leave a substantial part of the flues of the angle between them.

700,218. THUMB-LATCH FOR ADJUSTMENT-LEVER. JAMES MACFARLAN, Chicago, Ill., assignor to the McCormick Harvesting Machine Company, Chicago, Ill., a Corporation of Illinois. Filed Dec. 20, 1900. Serial No. 41,156. (No model.)

Claim.—1. A thumb-latch blank formed of sheet metal having a thin flat body and extensions in the plane of each body portion adapted to be pivotally connected to the lever and to the detent or pawl, and having a lug or projection arranged to extend in angular relation with respect to the plane of the body of said latch to engage the lever to limit the movement of said latch relative to said lever, as and for the purpose set forth.

2. A thumb-latch blank formed of sheet metal, having a thin flat body provided with extensions in the plane of each body to form means for pivotally attaching said latch to the lever and to the pawl or detent, said body provided with angular lugs arranged to engage the lever to limit the movement of said latch relative to said lever, as and for the purpose set forth.

3. A thumb-latch blank formed of sheet metal, having a thin flat body provided with extensions in the plane of each body, forming means of attaching said latch to the lever and to the pawl or detent, said body having lugs or wings arranged on opposite sides of the point of attachment of the latch to the lever and projecting in angular relation with respect to the plane of the body of each latch to engage the lever to limit the movement of each latch relative to each lever, as and for the purpose set forth.

4. A thumb-latch blank formed of sheet metal, having a thin flat body provided with extensions arranged in the plane of the body thereof to form means of attaching the same to the lever and in the detent or pawl, said latch provided with an integral lip forming a spring, as and for the purpose set forth.

700,214. HARROW. JAMES HANTRAIL, New Island, Ill. Filed Apr. 28, 1901. Serial No. 57,011. (No model.)

Claim.—1. The combination with a support, of an implement suitably bent to form a loop and provided with a shank, the shank adapted to be secured to said support and said loop snapping satisfactorily over said support, as and for the purpose set forth.

2. The combination with a support having transverse openings, of an implement provided with a shank adapted to be driven through such openings, said implement being formed into a loop arranged to snap over the exterior surface of said support when said shank is driven into place in said support, as and for the purpose set forth.

3. The combination with a holder, of an implement provided with a shank, said holder adapted to receive and rigidly hold said shank, said implement provided with a loop arranged to yieldingly grip the exterior surface of said holder, as and for the purpose set forth.

4. The combination with a support, of an implement provided with a shank terminating in a portion bent sharply into angular relation with said shank and terminating in a loop, the normal distance between said shank and the adjacent surface of said loop being less than the length of the exterior radius of said support, whereby when said shank is driven into said support said loop yieldingly snaps over the exterior surface of said support, as and for the purpose set forth.

5. The combination with a support, of an implement having a shank and an operating-stem, said implement between said shank and stem being bent in angular relation with respect to said shank and also into a loop, the radius of said loop being larger than the radius of curvature of said bend, whereby when said shank is driven into said support the loop yieldingly snaps over the exterior surface of said support, as and for the purpose set forth.

6. The combination with a tubular section having transverse openings therethrough, of an implement having a shank and a working stem, said implement between said shank and stem being bent into angular relation with respect to said shank, said angular portion terminating in a loop, as and for the purpose set forth.

7. In a harrow, a framework, supports mounted therein, said supports provided with transverse openings, and spring harrow-teeth formed with shanks adapted to be driven into said transverse openings, said shanks terminating in an angular portion, said angular portion being bent into a loop to form an operating-stem, said loop arranged to yieldingly snap over the exterior surface of said support when the shank is driven home.

700,215. WHEEL. JAMES HANTRAIL, New Island, Ill., assignor to McCormick Harvesting Machine Company, Chicago, Ill., a Corporation of Illinois. Filed Apr. 27, 1901. Serial No. 57,009. (No model.)

Claim.—1. A wheel composed of sheet-metal disks or plates, each of said plates or disks being bent outwardly or away from each other at the outer peripheries thereof, said outwardly-bent portions being bent or doubled back upon themselves to project in opposite directions, thereby forming laterally-extending flanges, the reversely-bent or doubled-back portions of one of said disks or plates having its edge turned over upon and under the laterally-extending flange of the other of said plates or disks, as and for the purpose set forth.

2. A wheel composed of sheet-metal disks or plates, each of said plates or disks being bent outwardly or away from each other at the outer peripheries thereof, said outwardly-bent portions being bent or doubled

back upon themselves to project in opposite directions, thereby forming laterally-extending flanges, one of said flanges to constitute the tread portion of the wheel, said flanges being arranged to engage and lock with each other, as and for the purpose set forth.

700,216. PIPE-GRAB. VALENTINE MATULA, Belmont, Tex., assignor of one-half to William Lee Foster, Belmont, Tex. Filed Nov. 27, 1901. Serial No. 52,914. (No model.)

Claim.—1. In a pipe-grab, a cylinder, standards attached thereto, a rope-held pivoted to the free ends of said standards, jaws hinged to said cylinder, means to hold the upper edges of said jaws against said standards, and means to swing said jaws from engagement therewith, substantially as shown and described.

2. In a pipe-grab, a cylinder, standards attached thereto, a rope-held pivoted to the free ends of said standards, jaws hinged to said cylinder, a leaf-spring attached to said cylinder and bearing against each said jaw, and means to lift said jaws, substantially as shown and described.

3. In a pipe-grab, a cylinder, standards attached thereto, a rope-held pivoted to the free ends of said standards, jaws hinged to said cylinder, a leaf-spring attached to said cylinder and bearing against each said jaw, a slidable plate mounted on said cylinder having a portion shaped to bear against said jaws to lift them, and means to limit the upward movement of said plate, substantially as shown and described.

4. In a pipe-grab, a cylinder, standards attached thereto, a rope-held pivoted to the free ends of said standards, jaws hinged to said cylinder, a leaf-spring attached to said cylinder and bearing against each said jaw, a slotted plate slidably mounted on said cylinder, and projections at each side of said plate having slanting upper surfaces to bear against the bottoms of said jaws, substantially as shown and described.

5. In a pipe-grab, a cylinder, standards attached thereto, one of said standards spaced apart from the inner side of said cylinder, a longitudinally-slotted plate slidably mounted between said cylinder and said standard, angular projections on each side of said plate, jaws hinged to said cylinder, means to hold said jaws against said standards, and means to raise said slotted plate to swing said jaws from said standards, substantially as shown and described.

6. In a pipe-grab, a cylinder, standards secured thereto, one of said standards spaced apart from the inner side of said cylinder, a longitudinally-slotted plate slidably mounted between said cylinder and said standard, angular projections on each side of said plate, a rope attached to said plate, ends pivoted to said standards and connected by a bolt for attaching the rope for raising and lowering the grab, jaws hinged to said cylinder, and a leaf-spring secured to said cylinder bearing against each jaw, substantially as shown and described.

700,217. BREACH-LOADING GUN. JOHN F. HENNS and EDWARD A. STEIN HANNAH, South Bethlehem, Pa., assignors, by mesne assignments, to Bethlehem Steel Company. Filed Nov. 7, 1900. Serial No. 606,744. (No model.)

Claim.—1. In a breach-loading gun having a fluid-containing receptacle-cylinder and a piston, in combination with breech mechanism, a cylinder and piston device mounted on the gun-body for operating such mechanism

ism, and means whereby pressure from the recoil-cylinder is transmitted directly to the operating-cylinder, substantially as and for the purpose described.

2. In a breech-loading gun having a fluid-containing recoil-cylinder and a piston, in combination with a breech mechanism, a movable device for operating the latter including a piston, a cylinder for the piston mounted on the gun-body, and means whereby pressure from the recoil-cylinder is delivered directly to said other cylinder, substantially as and for the purpose set forth.

3. In a breech-loading gun having a fluid-containing recoil-cylinder and a piston, in combination with a breech-closing device, and means for moving it to cause it to be locked and unlocked, means mounted on the gun-body and actuated by pressure of fluid from the recoil-cylinder transmitted during counter-recoil, to cause the breech-closing device to be unlocked, substantially as and for the purpose shown.

4. In a breech-loading gun having a fluid-containing recoil-cylinder and a piston, in combination with a breech-closing device and means mounted on the gun-body for causing the breech device to be locked, and connections between the recoil-cylinder and the locking means, whereby power derived from the pressure of fluid taken from the recoil-cylinder during counter-recoil, causes locking of the breech, substantially as and for the purpose described.

5. In a breech-loading gun, in combination with the breech mechanism thereof, a recoil-cylinder containing fluid, the piston in said cylinder connected with the gun-body, the recoil-spring, a movable device mounted on the gun-body actuated by fluid from the cylinder, under pressure during the return of the piston after recoil, and operative connections between such device and a movable part of the breech mechanism whereby the latter is unlocked during counter-recoil, substantially as and for the purpose described.

6. In a breech-loading gun having a fluid-containing recoil-cylinder and a piston moving therein and connected with the gun-body, in combination with movable breech mechanism, a second cylinder mounted on the gun-body and in communication with the recoil-cylinder, a piston in the second cylinder, and connections between the latter piston and the breech mechanism, whereby the movements of said second piston unlock and open the breech mechanism, substantially as and for the purpose described.

7. In a breech-loading gun having a fluid-containing recoil-cylinder and a piston moving therein and connected with the gun-body, in combination with the movable breech mechanism of the gun, a second cylinder mounted on the gun-body and in communication with the recoil-cylinder, a piston in the second cylinder, moved in one direction by pressure of fluid under pressure from the recoil-cylinder, connections between the latter piston and the breech mechanism, and a spring acting to move the second piston in a direction opposite to that in which it is moved by the fluid under pressure from the fluid causing the unlocking and opening of the breech mechanism and its movement by the spring closing and locking said mechanism, substantially as and for the purpose described.

8. In a breech-loading gun having a fluid-containing recoil-cylinder and a piston, in combination with the breech-plug mechanism for unlocking and withdrawing the plug, that remains inoperative during recoil, a second cylinder and piston mounted on the gun-body, connections between the same and the said plug-operating mechanism, and means whereby

by fluid under pressure is transmitted from the recoil-cylinder to the other cylinder during counter-recoil, substantially as and for the purpose set forth.

9. In a breech-loading gun having a fluid-containing recoil-cylinder and a piston, in combination with the breech-plug mechanism for unlocking and withdrawing the plug that has no movement relative to the gun-body during the recoil of the latter, a second cylinder and piston mounted on the gun-body, connections between the same and said plug-operating mechanism, a spring acting to move the recoil-piston forward, and connections between the two cylinders, whereby, during the action of said spring, fluid is transmitted from the recoil-cylinder to the other cylinder, substantially as and for the purpose shown.

10. In a breech-loading gun having a fluid-containing recoil-cylinder and a piston, in combination with the breech-plug mechanism for unlocking and withdrawing the plug that has no movement relative to the gun-body during the recoil of the latter, a second cylinder and piston mounted on the gun-body, connections between the same and said plug-operating mechanism, means whereby fluid under pressure is transmitted from the recoil-cylinder to the other cylinder during counter-recoil, and a valve for controlling the exit of fluid from said second cylinder, substantially as and for the purpose set forth.

11. In a breech-loading gun, the combination of a recoil-cylinder and piston, one of which is connected to the gun-mount and the other of which is attached to the gun, an operating-cylinder and its piston for the breech mechanism one of which is attached to the gun and the other of which is attached to the breech mechanism, and means for conveying fluid which connects the recoil-cylinder with the operating-cylinder, substantially as and for the purpose described.

12. In a breech-loading gun, the combination of a recoil-cylinder that is carried by the gun-mount, a piston for said recoil-cylinder which piston is attached to the gun, an operating-cylinder also attached to the gun and connected with said recoil-cylinder, and a piston in said operating-cylinder and connected to the breech mechanism, substantially as and for the purpose described.

13. In a gun, in combination with a fluid-containing recoil-cylinder, the piston moving therein and connected with the gun-body so as to be moved by the recoil thereof, the recoil-spring, the hollow piston-rod having its bore connected with the interior of the cylinder by a suitable fluid-conducting passage or port, a second cylinder connected with the bore of the piston-rod by suitable fluid-conducting passages, a piston moving in the second cylinder, and adapted to be moved in one direction by the pressure of fluid in its cylinder, and spring mechanism acting to return the piston after such movement, substantially as and for the purpose described.

14. In a gun, in combination with a fluid-containing recoil-cylinder, the piston moving therein and connected with the gun-body, so as to be moved by the recoil thereof, the recoil-spring, the hollow piston-rod having its bore connected with the interior of the cylinder by a suitable fluid-conducting passage or port, a second cylinder connected with the bore of the piston-rod by suitable fluid-conducting passages, a piston moving in the second cylinder, and adapted to be moved in one direction by the pressure of fluid in its cylinder, spring mechanism acting to return the piston after such movement, a movable valve to check the flow of fluid from the second cylinder, and means for moving said valve, substantially as and for the purpose described.

15. In a gun, in combination with a fluid-containing recoil-cylinder and a hollow piston moving therein and connected with the gun-body so as to be moved by the recoil thereof, a recoil-spring compressed by the movement of the piston, during recoil of the gun, a hollow piston-rod having its bore connected with that in the piston, a second cylinder connected with the recoil-cylinder by suitable fluid-conducting connections, a piston moving in the second cylinder adapted to be moved in one direction by the pressure of fluid in its cylinder, and spring mechanism to return said piston after it has been moved by the fluid, substantially as and for the purpose described.

16. In a gun, in combination with the gun-body, a hollow piston and piston-rod, connections between said rod and the gun-body, a recoil-cylinder in which the piston moves, containing fluid and provided with suitable ports or by-passes to allow passage of the fluid by the piston, a recoil-spring compressed by the movement of the piston, during recoil of the gun, and acting to return the piston after the recoil is completed, a second cylinder connected with the bore of the piston-rod by fluid-conducting connections, and a movable head moved by the pressure of fluid in the second cylinder, substantially as and for the purpose described.

17. In a breech mechanism for guns, the combination of a breech-block that is adapted to be closed by a rotary motion, a rear radially mounted on said breech-block, and a cam in the path of the rear and adapted to move the rear as the breech is closed, substantially as described.

18. In a breech mechanism for guns, in combination with the breech-

casing plug adapted to be locked in its breech-closing position by rotation, a spring-pressed firing-pin having a notched part, a spring-pressed firing-pin-holding ear, rotating with the plug, and having a trigger-engaging shoulder, a trigger around to which the ear-shoulder is brought by the locking rotation of the plug, and which has a nose to engage the ear-shoulder, either or both the ear-shoulder and the trigger-nose being beveled, so that, if the trigger is held pulled before the breech-plug is moved into locking position to carry its nose into the path of the ear-shoulder, the engagement of the trigger-nose and shoulder will cause the ear to be tripped to release the firing-pin, as the rotation of the plug, to cause its locking, is being completed, and a spring device to hold the trigger spring normally in position to keep its nose out of the path of the ear-shoulder, substantially as and for the purpose described.

19. In combination with the means for releasing the firing device of a recoil-mounted gun, the firing-lanyard connected with such device, a suitable guide for the lanyard directed on a part moving with the gun-body, to which guide the lanyard runs forward from the firing-device-releasing means, and a second guide over which the lanyard runs directed on a part stationary with reference to the recoiling part of the gun, each second guide being directed to the rear of the first guide, so that the lanyard runs rearward to it from the latter guide, substantially as and for the purpose described.

20. In a breech-loading gun, in combination with the breech-plug adapted to be locked in breech-closing position by axial rotation, a spring-pressed firing-pin having a radial arm with a cocking-notch, a spring-pressed ear moving with the breech-plug, as the latter is rotated, and having a nose to engage the notch on the firing-pin arm and a trigger-engaging shoulder, a cocking-ring journaled upon a bearing moving with the plug and having a cam-face to rotate the arm of the firing-pin, means for holding said ring from rotating with the plug, a trigger for tripping the ear after the plug has been rotated far enough to lock it from opening by the pressure brought upon it when the gun is fired, and a spring acting to hold the trigger normally urging to keep its ear-engaging nose out of the path of the ear-shoulder, substantially as and for the purpose described.

21. The combination of a gun mounted to recoil, a firing-lanyard, and a guide for said lanyard fixed with reference to the movement of the gun under recoil, and directed so that the lanyard runs forward from said guide to the gun when the latter is in its firing position, whereby when the gun moves rearward under recoil, there is no pull on the lanyard in the hands of the gunner, substantially as and for the purpose described.

700,218. AUTOMATIC FIRE-EXTINGUISHER. HARRY C. HENCKS, Cleveland, Ohio, assignor to Samuel W. Parsons, Cleveland, Ohio. Filed Feb. 27, 1901. Renewed Mar. 12, 1902. Serial No. 97,992. (No model.)

Claim.—1. A fire-extinguisher nozzle comprising a frame having a collar, a combustible plug having a screw-threaded connection with and extending through said collar, and a valve held in position on its seat by said plug and otherwise unimpeded in its opening movement in any direction.

2. A fire-extinguisher nozzle comprising a frame having a collar, a combustible plug removably mounted within said collar and plug extending through said collar, and a valve having a portion of its stem passing into said plug and normally positioned thereby.

3. A fire-extinguisher nozzle comprising a frame having a collar, a combustible plug removably mounted within and extending through said collar, said plug having a constricted passage-way therethrough, and a valve having a stem the outer end of which is enlarged and normally seats against the constricted portion of said passage-way, whereby said valve will be held to its seat and be positioned by said plug.

4. A fire-extinguisher nozzle comprising a frame, a combustible plug removably mounted therein, said plug having a flared outer end, and an independent igniter within said flared end.

5. In a fire-extinguisher nozzle, the combination with a valve-seat and frame, of a combustible plug carried by the frame, a valve held in position on said seat by said plug and otherwise unimpeded in its opening movement in any direction, and an initial igniter protected solely by said plug.

6. In a fire-extinguisher nozzle, a valve and valve-seat, a combustible valve-positioning device, and an igniter carried by said stem.

7. In a fire-extinguisher nozzle, a valve and stem, a combustible valve-positioning device having a central opening to receive the end of the valve-stem, and an igniter carried by said stem and extending through the said opening.

8. In a fire-extinguisher nozzle, the combination with a frame and a valve, of a combustible valve-positioning plug carried by the frame and having a central opening, the forward portion of which is flared, and an igniter located within the flared portion.

9. In a fire-extinguisher nozzle, the combination with a valve-seat and frame, of a combustible plug carried by the frame, and a valve held in position on said seat by said plug and otherwise unimpeded in its opening movement in any direction.

10. A combustible valve-positioning plug for fire-extinguisher nozzles having means for positioning the valve and having its rear portion forward with peripheral screw-threads, the forward portion being flared to afford a rigid initial combination.

11. A fire-extinguishing contrivance comprising a frame, a valve, an inflammable plug and an independent initial igniter for said plug carried by the valve-stem, the said frame containing a part terminating in a valve-seat and being adapted for connection with water-supply pipes, and the plug being removably connected with said frame and retaining the stem of said valve to its seat, all constructed and arranged substantially in the manner as and for the purpose set forth.

12. In a fire-extinguisher the combination with the valve and supporting structure thereof, of a combustible plug having connection with said structure and retaining the valve to its seat and an independent igniting medium positioned within and protected by the upper portion of said plug, all constructed and arranged substantially as and for the purpose set forth.

13. In a fire-extinguisher nozzle, the combination with a valve-seat and a frame, of a combustible plug carried by the frame, a valve held in position on said seat by said plug and otherwise unimpeded in its opening movement in any direction, and a combined lock and guard member carried by said plug.

14. In a fire-extinguisher the combination of the frame A, valve B, an inflammable plug C, initial igniter D carried by the valve-stem and a combined lock and guard member E, all constructed and arranged substantially as and for the purpose set forth.

700,219. FINE-REGULATOR. THOMAS R. HOGUE, Newton Center, and GEORGE E. TURNER, Waltham, Mass. Filed Aug. 28, 1901. Serial No. 77,791. (No model.)

Claim.—The combination with the column 10, the gage pipe, or tube, 16 extending therein and furnished with the float-chamber 17, the cover 18 for said chamber, and the elongated stuffing-box and guide 20 secured in a perforation of said cover, of the basket 26 having the weighted bottom 25, the stem 23 rigidly secured in said bottom and working through the stuffing-box 20, and controlling connections for connecting said stem 23 with a supply-valve.

700,220. MILK-PAIL SUPPORTER. ARTHUR J. MORELL and LOUIS W. BENTONVILLE, Minneapolis, Minn.; said MORELL assignor to said BENTONVILLE. Filed Dec. 14, 1901. Serial No. 98,196. (No model.)

Claim.—The combination with a pail and its ear, the ears having their edges suitably recessed; of pail-supporters, comprising body portions extending outward from the ears and downwardly-bent portions extending inward from the ears, arranged to engage the ears in said recesses and to bear upon the top portion of the pail, substantially as set forth.

700,220.

700,221. FLOOR-HINGE. THOMAS S. MORAN, Chicago, Ill. Filed Mar. 27, 1901. Serial No. 53,088. (No model.)

Claim.—1. In a floor rotatable hinge, the combination with the hinge-plate of a pair of interlocking elements associated therewith, one of which elements is fixed with respect to the plate and the other of which is disposed adjacent thereto and projects above the floor and is adapted to be moved by the foot of the operator into and out of locking engagement with the fixed element whereby the door is maintained open or permitted to close.

2. In a floor rotatable hinge, the combination with the hinge-plate and its containing casing of a fixed lateral projection carried by said plate and a sliding member carried by the top plate of the casing adapted to be moved into and out of lateral engagement with said projection to maintain the door open or permit it to close.

3. In a floor rotatable hinge, the combination with the hinge-plate of a series of fixed lateral projections carried by said plate and a sliding member disposed adjacent the plate and adapted to be moved into and out of lateral engagement with one of said projections, in the manner and for the purpose described.

4. In a floor-hinge, the combination with the hinge-plate and its containing casing of a pin extending transversely through said plate immediately below the top plate of the casing and projecting laterally therefrom, a slotted plate slidably secured to the under face of the top plate and movable into and out of engagement with the projecting ends of said pin, and means disposed on top of said top plate, connected with said slotted plate, adapted to be actuated by the foot of the operator.

700,222. EXTENSION-TABLE. CHARLES W. MUM, Detroit, Mich. Filed Feb. 16, 1901. Serial No. 42,861. (No model.)

Claim.—1. In an extension-table, the combination with the stationary section comprising a top and side rails, of an extension-section provided with a top or leaf and a side rail both adapted to be stored in the space enclosed by the top and sides of said stationary section, and means for automatically moving said extension side rail into alignment with said fixed side rail upon the movement of said extension top or leaf into the plane of said fixed top.

2. In an extension-table, the combination with the stationary section comprising a top and side rails, of an extension-section provided with a top or leaf and a side rail, both adapted to be stored in the space enclosed

by the top and side rails of said stationary section, and means for automatically moving said extension side rail into or out of alignment with said stationary side rail upon the corresponding movement of said extension top or leaf in or out of the plane of said stationary top.

3. In an extension-table, the combination with the stationary section comprising a top and side rails, of an extension-section having a leaf permanently carried thereby, an extension side-rail section corresponding to said leaf and hinged thereto, means for raising and lowering said leaf to move the same into or beneath the plane of said stationary top, and means operated thereby for swinging said side rail correspondingly in or out of alignment with said fixed side rail, whereby said extension-rail is automatically folded and stored by the extension of the table.

4. In an extension-table, the combination with the stationary section comprising a top and side rails, of an extension, a leaf carried thereby, a swinging link connection between said leaf and said extension-section permitting of raising and lowering of the former, an extension side-rail section hinged to said leaf and a connection between said swinging link and said hinged side-rail section, whereby the latter is turned into alignment with the fixed side rail or folded for storing by the corresponding raising or lowering of said leaf.

5. In an extension-table, the combination with stationary and extension sides, comprising extension-slides and an end rail of a leaf carried by said extension-section and having a swinging connection therewith whereby it may be raised or lowered, a bell-crank lever carried by said extension and rail having one arm in engagement with said leaf, a rod connected to the other arm of said bell-crank, and having a sliding engagement with said stationary section, and a stop for limiting the movement of said rod when the table is being extended whereby said bell-crank lever is actuated to swing said leaf upward into the plane of the stationary top.

6. In an extension-table, the combination with a stationary section and a movable top or leaf adapted to be stored therein, of a side-rail section carried by said leaf and movable in relation thereto from a position permitting of storing top a position complementary to said stationary section and means for automatically operating said extension side rail by the movement of said leaf.

7. In an extension-table, the combination with stationary and extension sections, of a rod longitudinally and centrally arranged being fixedly connected to one of said sections and having a sliding engagement with the other, a clamping-lever for locking said rod from its sliding movement, an operating-rod for said lever extending to the side of the table, and a crank-arm for actuating said rod and lever and locking the same in position for clamping.

8. In an extension-table, the combination with a stationary section and a movable top or leaf, of a side-rail section carried by said leaf and means for automatically moving said side-rail section relative to said leaf by the movement of the latter relative to said stationary top.

700,228. STEAM-CONDENSING SYSTEM. JOHN D. MORAN, Oswego, N. Y. Filed Oct. 21, 1900. Renewed Oct. 22, 1901. Serial No. 79,541. (No model.)

Claim.—1. A steam-condensing system having the single centrifugal pump provided with suction-pipes to the condenser and cooling-tower and a single discharge through which the water drawn from said tower and said condenser is elevated to the top of the cooling-tower, substantially as described.

2. A condensing system comprising a steam-condenser, a cooling device for the injection-water, and a single centrifugal pump maintaining the circulation of the cooling-water and the injection-water, and maintaining the partial vacuum in the condenser, substantially as described.

3. A steam-condensing system comprising a cooling-tower for the injection-water, a cooling-water circuit therefor, a steam-condenser, an injection-water circuit including the condenser, and a centrifugal pump included in both the cooling-water and injection-water circuits and maintaining the circulation thereof and maintaining vacuum on and the partial vacuum in the condenser, substantially as described.

4. A steam-condensing system comprising a condensing-water-cooling device, a condenser, a condensing-water pipe thereto from said cooling device, a centrifugal pump having a suction-dust opening into the condenser, and another suction-dust for the cooling-water from said cooling device, and a discharge communicating with the cooling device through which all the water drawn from said condenser and said cooling device is forced to maintain the circulation back through the cooling device and condenser, substantially as described.

5. In a steam-condensing system, a cooling-tower for the condensing-water, a condenser into which the exhaust-steam and injection-water are discharged, and a centrifugal pump having a high suction-power dust communicating with the interior of said condenser and another suction-power dust to the cooling-tower and for the cooling-water, and a common dis-

charge-dust through which the water from said suction-dusts is elevated back to the cooling-tower, substantially as described.

6. In a condensing system, a centrifugal pump having a case and a rotating runner therein provided with a series of radiating suction-passages at their outer ends discharging into the casing by centrifugal action, an axial suction-dust to the inner ends of said passages, a steam-condenser having its interior in direct suction communication with said dust and through the same with said passages, another suction-dust into the casing and through which said dust is maintained by the centrifugal action of the runner itself, a water connection to said dust, and a common discharge from the pump-casing, substantially as described.

7. In a condensing system, the combination of a condenser, a centrifugal pump comprising a casing having a discharge dust or opening, a rotary runner in said casing arranged to act centrifugally on the water therein to force the same under pressure through said discharge, said runner provided with a central water-chamber and radiating suction-passages therefrom at their outer ends discharging into the casing, an axial suction journal-pipe discharging into said chamber, a suction-dust from said pipe opening directly into said condenser, and a fluid-tight packing or joint for said journal-pipe, substantially as described.

8. In a condensing system, the combination of a condenser, a cooling-tower, a centrifugal pump having a casing provided with a discharge, a rotary runner in the casing arranged to act centrifugally on the water therein to force the same under pressure through said discharge, a suction-dust opening into the interior of the casing and connected by a liquid-passage to said cooling-tower, said runner having a central water-chamber, radiating suction-tubes at their inner ends opening into said chamber and at their outer ends discharging under centrifugal action into said casing, a hollow journal opening into said chamber and a suction-dust from said journal to said condenser, whereby the suction-tubes have direct suction communication with said condenser, substantially as described.

9. In a condensing system, the combination of a steam-chamber, a centrifugal pump comprising a casing and a rotary runner therein, said runner having a hollow journal rotating therewith, and a series of radiating suction-tubes rigid with the runner and at their outer ends discharging into said casing and at their inner ends having liquid and suction communication with said hollow journal, a suction-dust from said chamber to said hollow journal, and a coupling between said dust and said journal and in which said journal retains comprising a packing-joint within the coupling and around the journal, substantially as described.

10. In an exhaust-steam-condensing system comprising a cooling-tower and condenser, a centrifugal pump included in the cooling-water circuit and in the condensing-water circuit, in combination with suction and discharge dusts, whereby the single pump maintains the circulation of the cooling-water and the condensing-water and creates the partial vacuum in the condenser, and whereby said cooling-water and conden-

ing-water are both drawn into and communicated in and discharged from the single pump, substantially as described.

11. The combination, in a condensing system, of a steam or vacuum chamber, a centrifugal pump having a casing with a discharge and a rotary centrifugally-acting runner in said casing having radiating suction-passages at their outer ends discharging into the pump-casing, an axial suction-pipe rotating with the runner and with which the inner ends of said passages have suction and liquid communication, a rigid coupling into which said pipe projects and in which it rotates, a suction-dust from said coupling to said chamber, and a packing-joint in the coupling forming a liquid-tight joint between the same and said rotating axial suction-pipe, substantially as described.

12. In combination, in a condensing system, a bed-plate, a centrifugal pump casing covered thereto, a head of said casing having a central opening, a horizontal coupling closed at its outer end and having its open inner end rigidly secured to said casing-head around said opening therein, a support for said coupling, a condenser-chamber rigidly secured on said coupling and having the suction opening or passage thereto, and a rotary runner-head in said casing and creating suction through said coupling and condenser to draw the liquid therefrom into the pump-casing and discharge the same therefrom under pressure, substantially as described.

13. In combination, in a condensing system, a condenser, a centrifugal pump, having a casing with a discharge, and a rotary runner having outwardly-extending suction-passages discharging into the casing, a hollow journal rigid with the runner and in direct liquid and suction communication with the inner ends of said passages, a tube or casing in direct liquid and suction communication with said condenser and said hollow journal and into which said journal extends, and a packing-joint in said casing and around said journal, substantially as described.

14. A condensing system comprising in combination, a centrifugal pump shell having a fixed casing rigid with and extending laterally therefrom, a condenser mounted on and discharging into said casing, a rotary runner in the shell having a hollow journal projecting and opening into said casing, said runner provided with suction-passages discharging into the shell and in direct suction and liquid communication with said journal, substantially as described.

15. A condensing system comprising in combination, a centrifugal pump shell having a fixed casing rigid therewith, a diaphragm-condenser opening into said casing, a rotary runner in said shell having driving means and a hollow journal extending into said casing and in direct liquid and suction communication with said condenser, said runner having suction-passages discharging into said shell and having direct liquid and suction communication with said hollow journal, whereby said runner creates the necessary vacuum in said diaphragm-condenser, substantially as described.

16. A steam-condensing system having a single pump provided with suction-dusts acting on the condenser and cooling device and a single discharge through which the water drawn from said cooling device and from said condenser is discharged and whereby the circulation is maintained in the cooling and condenser circuits, substantially as described.

17. A condensing system comprising a condenser having a steam-inlet, a water-inlet and a discharge, in combination with a centrifugal pump having a discharge, and having a suction-dust in direct suction communication with said discharge of said condenser whereby the single pump draws the water and vapors from said condenser and maintains a partial vacuum therein, substantially as described.

18. A condensing system comprising a centrifugal pump having a discharge-dust, in combination with a condenser mounted on the pump-casing, said casing having a suction-dust from the pump in direct suction communication with said condenser, whereby the single pump draws the water and vapors from the condenser and maintains a partial vacuum therein, substantially as described.

19. A condensing system comprising a cooling device, a steam-condenser, and a single pump included in the cooling-water and condenser-water circuits and maintaining the circulation of the water in said circuits and the partial vacuum in the condenser, substantially as described.

20. A condensing system comprising a centrifugal pump having independent suction-dusts and a runner creating different degrees of suction through said dusts, said pump having a single discharge, in combination with a condenser in direct suction communication with one of said dusts, and a cooling device communicating with the other dust, substantially as described.

21. In a condensing system, a condenser, in combination with a centrifugal pump having a runner with suction-dusts in direct suction communication with said condenser, whereby the single pump draws the water and vapors from the condenser and maintains the partial vacuum therein, substantially as described.

22. A condensing system comprising a centrifugal pump having a runner with suction-dusts discharging into the pump-casing, a steam-chamber in direct suction communication with said chamber, whereby the partial vacuum is maintained therein, said pump having another suction-dust opening through its casing independently of said runner, a water-circuit

maintained through said casing-dust, said pump having a single discharge, substantially as described.

23. In a condensing system, the combination with a condenser of a centrifugal pump in direct action communication with said condenser, whereby the single pump maintains the partial vacuum therein and draws the water and vapors therefrom, substantially as described.

700,224. CENTRIFUGAL PUMP. JOHN D. McRAE, CHICAGO, ILL.
Filed Mar. 12, 1901. Serial No. 22,224. (No model.)

Claim.—1. In a centrifugal pump, a pump-casing having a discharge, a rotary pump-runner exteriorly formed with runner-arms to act centrifugally on the liquid in the casing and force the same through said discharge, said casing forming an annular water-space circumferentially around said runner, said runner provided with a series of suction-tubes of substantially uniform area and form in cross-section throughout and at their outer ends discharging into said annular water-space, and an axial suction-dust in direct action communication with the inner ends of said tubes, substantially as described.

2. In a centrifugal pump, in combination, a casing having a suction-opening and a discharge, and a rotary runner therein comprising a hollow hub, radiating arms or blades rigid with the hub, and suction-tubes arranged along said arms and at their inner ends opening into said hub, and an axial suction-pipe opening into and rigid with said hub, substantially as described.

3. A centrifugal pump comprising a casing, and a rotary runner acting on the liquid in the casing, to force the same therefrom under centrifugal pressure, said runner provided with radiating suction-passages at their outer ends discharging into the casing, an axial suction-pipe or duct in liquid and action communication with the inner ends of said passages, said passages formed at their inner ends with curved contracted portions, substantially as described.

4. In combination, in a centrifugal pump, a casing having a discharge, a rotary pump-runner exteriorly formed to drive the water centrifugally and circulate the same within said casing, and provided with outwardly-extending suction-passages consisting of suction-tubes of substantially uniform area and form in cross-section throughout and having exposed outer ends opening directly into the space around said runner, and an axial suction-dust to the inner portions of said passages, substantially as described.

5. A centrifugal pump comprising a casing having a discharge and a suction dust opening directly into the interior thereof, a rotary pump-runner in the casing exteriorly formed to act centrifugally on the liquid within the casing and force the same through said discharge, said runner

provided with outwardly-extending suction-passages at their outer ends discharging directly into the casing, and a suction-dust in direct action communication with the inner ends of said suction-passages, substantially as described.

6. In a centrifugal pump, the combination of a pump-casing having a circumferential discharge, a rotary runner in the casing comprising a hub and runner-arms formed to act centrifugally on the water in the casing in driving the same outwardly to and around the circumferential portion of the casing, suction-tubes secured in the hub between said arms and extending outwardly along said arms and at their outer ends discharging into the circumferential portion of the casing, a hollow suction-journal in direct action communication with the inner ends of said tubes, a suction-dust in communication with said journal, and a tight joint for said journal, substantially as described.

7. In a centrifugal pump, the combination of a pump-casing having a discharge, and a suction-dust opening directly into the interior of the casing, a rotary pump-runner exteriorly formed to act centrifugally on the water in the casing to create suction through said inlet and drive the water through said discharge, a suction-dust rigid with and extending from said casing, said runner provided with a hollow suction-journal extending into and rotating in said dust and with suction-passages at their outer ends discharging into the circumferential portion of the casing and at their inner ends in direct action communication with said journal only, and a tight joint in said dust and around said journal, whereby water is drawn into the casing through said inlet and also through said journal and passages, substantially as described.

8. In combination, a supporting-frame, a centrifugal-pump casing having an end opening, an outwardly-extending coupling secured thereto having a closed outer end and an induction-opening, a rotary runner, a drive-shaft therefor, a hollow journal rigid with the runner and projecting into said coupling, said runner having radiating suction-passages communicating with said journal, a packed joint in said coupling around said journal, and adjusting means for said joint extending to the exterior of said coupling, substantially as described.

9. In a centrifugal pump, in combination, a casing having a discharge, a rotary runner therein comprising a hub having radiating arms and a shaft, a hollow journal rigid with said hub and provided with a packed joint, and radiating suction-tubes rigid with the hub and arranged between and extending longitudinally of said arms, the outer ends of the tubes discharging into the casing and the inner ends thereof opening into said journal.

10. In a centrifugal pump, the combination of a pump-casing having a discharge, a rotary pump-runner comprising a hub, an axial suction-dust, outwardly and rearwardly extending runner-arms and a series of suction-tubes at their inner ends secured in the hub in action communication with said dust and from thence extending outwardly along and conforming to the front faces of said arms, said casing forming a water-space circumferentially around said runner, the outer ends of said tubes opening directly into said space, substantially as described.

11. In a centrifugal pump, in combination, a rotary runner having a hollow journal and a series of suction-tubes at their inner ends in direct action and liquid communication with said journal and having their open outer ends projecting beyond the outer diameter path of the runner itself, substantially as described.

12. In a centrifugal pump, the combination of a runner comprising outwardly-projecting runner-arms and rigid suction-tubes at their inner ends in direct action communication with a suction-dust, the outer open ends of the tubes projecting beyond the circle in which the outer ends of said arms move, and each cut off at an angle, substantially as described.

13. In combination, in a centrifugal pump, a pump-runner having an axial suction-dust and a series of outwardly-extending suction-passages opening into the pump-casing at their outer ends and at their inner ends opening into said suction-dust, each suction-passage having an internal oppositely tapered or curved contraction.

14. In combination, in a centrifugal pump, a rotary pump-runner having a hollow hub with a supply or suction dust-thereinto and outwardly-projecting suction-passages at their inner ends communicating with said dust and at their inner portions provided with oppositely-tapered or double-cone obstructed suction nozzles or portions, substantially as described.

15. A centrifugal-pump runner comprising a hollow hub with radiating runner-arms and having a shaft and a hollow journal, a suction-dust receiving said journal, a packed joint in said dust for said journal, and a series of inwardly-projecting removable suction-tubes between said arms and at their inner ends secured in said hub, substantially as described.

16. In a centrifugal pump, in combination, a pump-casing having a circumferential water-space and a discharge, a rotary pump-runner exteriorly formed to act centrifugally on the liquid in the casing and drive the liquid to and circulate the same in said space, said runner provided with suction-passages of substantially uniform area and form in cross-section

tion throughout having longitudinally-exposed tube-like outer ends discharging directly into said space, and a suction-dust in direct action communication with the inner ends of said passages, substantially as described.

17. In combination, a centrifugal-pump shell, a casing rigid with and extending laterally therefrom, a rotary pump-runner having a hollow journal in said casing, a packed joint in said casing for said journal, a gland in the casing for said joint, gland-adjusting means extending to the exterior of the casing, a suction-dust to the casing and said journal, said runner having radiating suction-passages communicating with said journal and discharging into the pump-shell, substantially as described.

18. In combination, a centrifugal-pump shell having a laterally-projecting casing, a rotary pump-runner having a hollow journal in said casing and suction discharge-passages from the journal opening into the shell, a packed joint within the casing around said journal, a gland on the journal, means holding the gland against rotation, a dust opening into said casing opposite said gland, said gland having an inlet-opening establishing liquid and action communication from said dust through said journal, and an adjusting-bolt passing through the casing to longitudinally adjust the gland, substantially as described.

19. In a centrifugal pump, the combination of a pump-casing having a circumferential water-space or shell with a discharge, a rotary pump-runner in said casing, surrounded by said water-space, and comprising a hub and outwardly-projecting runner-arms, said runner provided with a projecting hollow journal and a series of suction-passages at their inner ends opening into said journal and at their outer ends projected beyond said arms and discharging directly into said water-space within the casing, a suction-dust in direct action communication with the outer end of the journal, and a joint around an intermediate portion of said journal and shutting off direct communication between said dust and the interior of the pump-casing, substantially as described.

20. In a centrifugal pump, the combination of a pump-casing having a discharge, a coupling extending axially from said casing and having a suction-opening, a pump-runner in said casing and formed exteriorly to act centrifugally on the liquid in the casing and from the same therefrom through said discharge, said casing having a suction-dust opening directly thereto at the exterior of said runner, said runner formed with suction-passages at their outer ends discharging into the casing, a hollow journal in action communication with the inner ends of said passages, said journal and fitting snugly in said coupling and at its outer end in direct action communication with said suction-opening of said coupling, and a packing in said coupling and around said journal, substantially as described.

21. In combination, a centrifugal-pump casing having a discharge, a rotary runner having suction-dusts discharging into the casing and a hollow journal discharging to the inner ends of said passages, an inlet-dust, a coupling therefrom to said hollow journal placing the journal in direct action communication with said dust and a packed joint between the journal and coupling and comprising an adjustable gland in the coupling and receiving said journal and held against axial movement, and having a side inlet-opening, substantially as described.

22. In a centrifugal pump, the combination of a pump-casing having a circumferential water-space with a discharge, a rotary pump-runner fixed in the casing and surrounded by said space and exteriorly formed to force the water in the casing centrifugally into said space and circulate the same therein, said runner provided with a hollow journal and with radiating suction-passages at their inner ends opening into said journal and having their outer ends projected beyond the outer circle of movement of said runner and discharging directly into said water-space, a supply or suction dust opening to said hollow journal, and a liquid-tight joint around said journal, substantially as described.

23. A centrifugal pump having its runner provided with a hollow suction-journal, a casing having an inlet-part, said journal projecting into said casing and having an inlet-opening therein, a packed joint in the casing for said journal comprising a gland in which the journal rotates, means for holding the gland against axial movement, and means accessible from the exterior of the pump for adjusting the gland longitudinally of the journal, substantially as described.

24. In combination, a casing, a rotary pump-runner therein having a projecting hollow suction-journal, a T-coupling secured to the casing and receiving the journal, packing in the coupling around the journal, a sleeve in the coupling embracing the journal for adjusting the packing, and a screw from the exterior of the coupling for adjusting said sleeve longitudinally, substantially as described.

25. In combination, a centrifugal-pump casing having a coupling secured to a head thereof with a closed outer end and an annular internal shoulder, a pump-runner having a hollow suction-journal projecting into said casing, packing in the coupling around said journal and at said shoulder, a sleeve in the coupling around said journal and opposing said packing and having a side inlet-opening and a closed outer end, a pin passing through said end to the outer end of the coupling, and a screw adjustable through the outer end of the coupling and engaging said pin, substantially as described.

26. A centrifugal-pump runner having radiating suction-passages provided with contracted suction-nozzles at their inner ends, and a suction-dust discharging to the inner ends of said passages, substantially as described.

27. A centrifugal-pump runner having radiating suction-passages and separate suction-nozzles or contracted sections included therein, and an axial suction-dust discharging to said passages, substantially as described.

28. A centrifugal-pump runner comprising radiating suction-passages at their outer ends discharging centrifugally into the pump-casing and an axial supply-dust to their inner ends, separate contracted suction nozzles or nozzles included in said passages and means for securing the same, whereby various nozzles can be used interchangeably with the same passages, substantially as described.

29. A centrifugal-pump runner having an axial supply-dust, and radiating suction-passages opening into said dust, separate contracted pipe sections or nozzles in said passages, and outwardly-projecting suction-tubes at their inner ends secured in said passages in outward communication of said nozzles, substantially as described.

30. A centrifugal-pump runner having a hollow hub formed with radial passages, shoulders at the inner ends thereof, two-sections in said passages at their inner ends abutting against said shoulders, and outwardly-projecting suction-tubes at their inner ends removably secured in said passages and abutting against said sections, substantially as described.

31. A centrifugal-pump runner having a hollow hub with an axial suction-dust, rigid radiating runner-arms and outwardly-extending suction-tubes arranged between said arms and creating suction in and drawing the liquid from said dust through the centrifugal action caused by the rapid rotation of the runner, said tubes at their inner ends independently and removably secured in said hub, substantially as described.

32. A centrifugal-pump runner, having a hollow hub and an axial supply-dust therein, and outwardly-projecting suction-tubes therefrom having removable contracted suction-sections located in said hub, whereby the tubes can be employed with or without said sections.

33. In a centrifugal pump the combination of a pump-casing having a circumferential discharge and a suction-dust opening directly into said casing, a rotary pump-runner rotating close to the walls of the casing and creating suction through said dust by centrifugal action on the liquid in the casing at the exterior of the runner, a hollow journal for said runner, a suction-dust in direct communication therewith, a packed joint around said journal, said runner having radiating suction-passages at their outer ends discharging into the circumferential portion of the pump-casing and at their inner ends all in communication with said hollow journal and radiating suction-passages that off from action communication except through said hollow journal.

34. A centrifugal pump comprising a casing having a discharge and an axial suction-dust opening into the interior of the casing at the exterior of the runner, and a rotary runner in the casing, exteriorly formed to centrifugally drive the water in said casing to create suction through said axial dust, and having suction-passages throughout discharging centrifugally into the casing, and a suction-dust discharging into and supplying said passages, the capacity of said passages being different from that of said casing suction-dust, substantially as described.

35. In a centrifugal pump, the combination of a pump-casing having a discharge, a rotary pump-runner therein and comprising radiating runner-arms acting centrifugally on the water in the casing to force the same therefrom under pressure and create suction therein, said runner provided with a hollow journal, a suction-dust in which said journal rotates, said runner formed with radiating suction-passages arranged longitudinally of said arms with their outer ends and portions exposed at the front faces of said arms and discharging directly outwardly about at the ends of the arms and with their inner ends in direct action communication with said hollow journal, substantially as described.

36. In a centrifugal pump, the combination of a pump-casing, a pump-runner in the casing having radial suction-passages at their outer ends discharging into the casing, a hollow journal rigid with the runner and in communication with the inner ends of said passages, a T-coupling secured to the casing, said journal extending longitudinally into one branch of the T, another branch of the T forming a suction-opening, a packed joint in said first-mentioned branch of the T and around said journal, a bushing arranged longitudinally in said coupling and around and projecting beyond the journal end and having an opening establishing action communication between said journal and said suction-opening of the T, and means for adjusting said bushing longitudinally of said journal, substantially as described.

37. In a centrifugal pump, the combination of a pump-casing, a T-coupling secured thereto, a pump-runner in the casing having a hollow journal projecting into and provided with a tight joint in one of the branches of said T, a bushing arranged longitudinally in said coupling around said journal and maintaining said joint, said bushing having a side opening

opposite the intermediate branch of said T, a dent secured on said side branch of the T, the remaining branch of the T being closed and provided with means for adjusting said bushing, substantially as described.

39. In a centrifugal pump, the combination of a pump-casing having a discharge and a lateral extension with a supply-opening, a rotary pump-runner in the casing exteriorly formed to centrifugally drive the water in the casing and force the same through said discharge, said runner having outwardly-extending outlet-passages discharging into the casing and a hollow outlet-journal discharging into said passages and extending longitudinally into said extension, a packed joint for said journal, a longitudinally-slidable bushing fitted on and projecting beyond said journal and through which motion communication is maintained between said journal and said opening said bushing fitted snugly within and approximately throughout the length of said extension, and means for adjusting said bushing, substantially as described.

40. In a centrifugal pump, the combination of a pump-casing, a rotary pump-runner therein having a hollow outlet-journal and provided with outlet-passages at their inner ends in direct motion communication with said journal and at their outer ends opening outwardly directly into the interior of said casing beyond the outer circle of movement of the runner itself, the planes of said discharge-openings of said passages being inclined in the circle in which said discharge ends of the passages move, substantially as described.

41. In a centrifugal pump, the combination of a pump-casing having a discharge, a rotary pump-runner therein, said casing forming a water-space circumferentially around said runner, said runner exteriorly formed to act centrifugally on the water in the casing in driving the same therefrom through said discharge, and provided with outwardly and rearwardly curved tapered outlet-passages at their outer ends opening outwardly directly into said water-space so that the water therein sweeps transversely across said open ends as the runner rotates, an axial outlet-dust in motion communication with the inner ends of said outlet-passages and means shutting off said outlet-dust from communication with the casing interior except through said passages, substantially as described.

700,225. AUTOMATIC UNLATCHING DEVICE FOR ANIMALS AND FIRE ESCAPE AND EXTINGUISHER. GEORGE P. NEAL, Bismarck, Ind. Filed Aug. 7, 1901. Serial No. 71,398. (No model.)

Claim.—1. In a device of the class described, the combination with a cup or cylinder having a nozzle, and means for delivering water-pressure to said cup, of a piston movable in said cup or cylinder in response to the pressure, a piston-rod connected to the piston, a locking-rod rigidly connected to the piston-rod, outside the cup or cylinder and a hanger-ring holder through which the locking-rod passes, said locking-rod being adapted to secure the hanger, the nozzle being so disposed that the piston passes the opening in same and permits the flow of water after the hanger-ring has been unlatched.

2. In a device of the class described, the combination with a water supply pipe, of a cup or cylinder having a nozzle and having its outer end closed and being screw-threaded to the pipe at its other end and provided with legs whereby it can be screwed into position, a hanger-ring holder having eyes, a piston movable in the cup or cylinder and a piston-rod connected to the piston, a locking-rod slidable through the eyes and a screw-rod rigidly connected to the piston-rod and the locking-rod, said parts being so disposed and related that the water-pressure lifts the piston and moves the locking-rod and after the piston has passed the nozzle the water-pressure flows out therefrom.

700,226. GRINDING-MACHINE. MICHAEL W. HENRI, Port Washington, Wis., assignor to Western Implement Company, Port Washington, Wis. Filed Dec. 30, 1901. Serial No. 57,708. (No model.)

Claim.—1. A grinding-machine comprising a base, a bracket in spring-controlled pivotal connection with the base, a tilt-frame hanging in the bracket under arms of the same, a frame-controlling lever, a standard, a swing-arm in connection with the standard, a grinding device hanging in the swing-arm, grinding device drive-gear having the main wheel thereof provided with a rounded end eye branch having a base, a swing-arm in connection with the standard having notched opposite side legs and another leg ahead of these, and an open-end link adjustable to engage the standard-branch base and notched legs of the swing-arm outside of an eccentric constituting part of the drive-gear or to engage the standard-branch eye outside of said arm against the leg ahead of these, and

thereof provided with an eccentric, and a rocker outside of the eccentric in connection of its ends with said arm and a branch of said standard.

2. A grinding-machine comprising a base, a bracket in spring-controlled pivotal connection with the base, a tilt-frame hanging in the bracket under arms of the same, a lever on said base opposing a cam-bar of the frame and provided with legs arranged to face opposite sides of a bracket-bar, a standard, a swing-arm in connection with the standard, a grinding device hanging in the arm over the clamp consisting of said bracket, tilt-frame and lever, and means for imparting rotary motion to the grinding device simultaneous with an oscillation of said arm.

3. A grinding-machine comprising a base, a bracket in pivotal connection with the base, a tilt-frame hanging in the bracket under arms of the same, a lever on said base opposing a cam-bar of the frame and provided with legs arranged to face opposite sides of a bracket-bar, a standard, a step in pivotally-adjustable connection with the standard opposite said bracket, a spring in adjustable tension connection with the step and connected to said lever, a swing-arm in connection with said standard, a grinding device hanging in the arm over the spring-controlled clamp consisting of the standard bracket, tilt-frame and lever, and means for imparting rotary motion to the grinding device simultaneous with an oscillation of said arm.

4. A grinding-machine comprising a standard in rotative one adjustable on the other, an arbor seated in the upper standard-section, a detachable branch of the standard constituting a clamp for the arbor, a swing arm on said arbor, a grinding device hanging in the swing-arm, means for imparting rotary motion to the grinding device simultaneous with an oscillation of said arm, and a sickle-bar clamp arranged under said grinding device.

5. A grinding-machine comprising a base, a sickle-bar clamp in pivotal connection with the base, a standard, a fork in pivotally-adjustable connection with the standard and having its arms at an acute angle to each other, the lower arm being arranged to oppose the clamp; a clamp-controlling spring in adjustable tension connection with the upper arm of the fork, a swing-arm in connection with said standard, a grinding device hanging in the arm over the clamp, and means for imparting rotary motion to the grinding device simultaneous with an oscillation of said arm.

6. A grinding-machine comprising a base, a sickle-bar clamp in pivotal spring-controlled connection with the base, a standard, a swing-arm constituting a grinding-device hanger in connection with the standard, grinding-device drive-gear having the main wheel thereof provided with an eccentric, and a swing-arm rocker engageable with the eccentric, but translatable to constitute a support for said arm and parts therewith in stationary position.

7. A grinding-machine comprising a standard and drive-gear, a swing-arm in connection with the standard, and an open-end link adjustable in connection with a standard branch and said arm to straddle an eccentric of the drive-gear or to clear said eccentric and hold the standard arm stationary.

8. A grinding-machine comprising a drive-gear, a standard provided with a rounded end eye branch having a base, a swing-arm in connection with the standard having notched opposite side legs and another leg ahead of these, and an open-end link adjustable to engage the standard-branch base and notched legs of the swing-arm outside of an eccentric constituting part of the drive-gear or to engage the standard-branch eye outside of said arm against the leg ahead of these, and

9. A grinding-machine comprising a standard provided with an arbor-seat, an arbor-clamp attachable to the standard, a swing-arm on the arbor that is held in its seat by said clamp, a grinding device hanging in the swing-arm, means for imparting a rotatory motion to the grinding device, a stop on the standard limiting play of the swing-arm under hand control, and a sickle-bar clamp arranged under said grinding device.

10. A grinding-machine comprising a standard, a swing-arm in connection with the standard, a grinding device hanging in the swing-arm, a sickle-bar clamp arranged under the grinding device, a spur-wheel having a pinion-hub loose on a lateral base of said arm, a pinion on the grinding-device arbor in mesh with said spur-wheel, an eccentric-hub-driving spur-wheel loose on an arbor constituting the swing-arm axis, an open-end link straddle of a standard branch and the eccentric-hub, and legs on the eccentric arm engaging branches of the link.

700,227. LOCK FOR SLIDING DOORS. AUGUSTUS NEWELL, Pasadena, Cal., assignor to the Perfect Sliding Door Company, Los Angeles, Cal., a Corporation of California. Filed Oct. 13, 1900. Serial No. 33,989. (No model.)

Claim.—1. In a lock, the combination of a frame; a latch pivoted in said frame and provided with a substantially horizontal way; a sliding bolt carried in said way; a stop to intercept the bolt to prevent the latch from rising when the bolt is in latching position; said bolt being arranged to be rotated to escape the stop to allow the latch to be lifted for unlatching.

2. In a lock, the combination of a frame; a latch pivoted in the frame and furnished with a horizontal way and with a catch; a sliding bolt to slide along said way; a stop on said frame above said way to intercept the bolt to prevent the latch from rising when the bolt is in latching position; a ward pivoted to the bolt under the catch carried by said latch, and furnished with a catch to engage said latch-carried catch; and a spring to normally hold the ward in catching position.

3. In a lock, the combination of a frame; a latch pivoted in said frame and furnished with a horizontal way and with a catch; a sliding bolt to slide along said way and provided with a stop; a stop on said frame above the way to intercept the bolt to prevent the latch from rising when the bolt is in latching position; a ward pivoted to the bolt under the catch carried by said latch, and furnished with a catch to engage said latch-carried catch; a spring to normally hold the ward in catching position; and a dog to normally engage the bolt to intercept the stop thereon.

4. In a lock, the combination of a pivoted latch furnished with a way; a bolt to slide in said way and furnished with a stop; and a spring-pressed dog pivoted to said latch to normally engage said bolt and intercept the said bolt-stop.

5. In a lock, the combination of a latch furnished with a hollow way and with a circular key-shaft way; a cylindrical key-shaft fitted in the key-shaft way and seated longitudinally from end to end, and furnished with a peripheral groove to correspond with the hollow way; a bolt sliding in said hollow way and peripheral groove; a key to enter the longitudinal slot to throw the bolt, and furnished with a stop to project outside the slot; and a key-stopping ring on the key-shaft and fitting against the latch to intercept the stop of the key, to stop the key in position for appropriately engaging the bolt.

6. The combination with a latch and a bolt sliding in said latch, of a cylindrical key-shaft to rotate in said latch, and furnished with a peripheral groove to receive said bolt; and a ring around the key-shaft to form a stop to limit the insertion of the key substantially as set forth.

7. The combination of a latch; a bolt sliding on said latch; a key-shaft seated longitudinally and furnished with a peripheral groove to receive the bolt; a key for the longitudinal slot of the key-shaft to engage the bolt to withdraw it when turned in one direction, and to engage the bolt to expel it from the key-shaft when turned in the other direction; and a catch to normally hold the end of the bolt in the path of the key and release said bolt to allow its expulsion.

8. In a lock furnished with a gravity-latch; a main catch-plate adapted for attachment to the door-post and furnished with a sliding latch-plate.

9. In a lock, the combination of a catch-plate furnished on its side with a stud; a latch-plate furnished with a slot fitted on said stud; and a cover in the stud to hold the latch-plate in position.

10. In a lock, the combination of a catch-plate; a latch-plate at the rear of said catch-plate and furnished with a slot; and a cover inserted through the slot for adjustably securing the latch-plate on the catch-plate.

700,228. CHARCOAL-BRATER. THOMAS O'BRIEN, Paris, France. Filed Feb. 12, 1902. Serial No. 98,971. (No model.)

Claim.—1. In a portable stove, the combination of a metallic casing closed at its lower end and open at its upper end, and having an opening adjacent to its bottom; a pot of fire-resisting material arranged in the casing and on the bottom thereof, and having a grate at an intermediate point of its height, and an opening below said grate, registered with the opening in the casing, and also having the exterior flange snugly fitting in the casing, and the exterior recess below said flange and above the grate whereby the space D is formed, a suitable cover on the casing, and a damper connected to the casing for controlling the opening therein.

2. In the portable stove described, the combination of a metallic casing closed at its lower end and open at its upper end, and having an opening adjacent to its bottom, and a leg on its side adjacent to its upper end; said leg being provided with a vertically-disposed hydraulic-chamber, a cover having a depending stud adjacent to its perimeter, journaled in the leg-hole-slot of the leg, and provided at its lower end with an enlargement, a handle connected to the casing, a damper also connected to the casing, and arranged to control the opening therein, and a pot of fire-resisting material arranged in the casing and on the bottom thereof, and having a grate at an intermediate point of its height, and an opening below said grate, registered with the opening in the casing, and also having the exterior flange snugly fitting in the casing, and the exterior recess below said flange and above the grate whereby the space D is formed.

700,229. PROCESS OF MAKING SOAP. THOMAS FAIRHALL, Alexandria, Egypt. Filed Aug. 13, 1902. Serial No. 57,894. (No specimens.)

Claim.—The process described consisting in mixing cold cotton-seed oil and flour containing gluten together, allowing the mixture to stand and then mixing with the said mixture caustic soda, substantially as described.

700,230. FURNACE. WILIAM W. FRISLEY, Efforton, Iowa. Filed Feb. 10, 1902. Serial No. 98,984. (No model.)

Claim.—1. In combination, a furnace having a ceiling and a fire chamber, an arch forming the division-wall between said chambers extending entirely from the rear wall of the furnace to the front wall thereof, a filling and discharge opening in said front wall, extension of the side walls of the fire-chamber projecting beyond the front wall of the furnace, and an inclined grate located in the projecting walls of the fire-chamber and extending in advance of the front wall of the furnace.

2. In combination is a furnace provided with a fire and a ceiling chamber, an arch forming the division-wall between the same, an inclined grate in the fire-chamber in advance of said arch and a fire located in each side wall of the furnace in communication with each of said chambers, and with the exterior of the furnace, substantially as described.

3. In combination is a furnace having a fire and a ceiling chamber, an arch forming the division-wall between the same, an inclined grate in the fire-chamber in advance of said arch, and a fire located in each side

wall of the furnace in communication with each of said chambers, said flue extending through the top of the furnace, a damper located on said top and a damper arranged in each flue between said chambers, substantially as described.

700,281. GRAIN-DRILL. CHARLES E. PETERSON, Springfield, Ohio, assignor to the Thomas Manufacturing Company, Springfield, Ohio, a Corporation of Ohio. Filed Apr. 12, 1902. Serial No. 108,986. (No model.)

Claim.—1. In a grain-drill, the combination, with a hopper provided with grooved locking-plates on its under side, and a distributor-chest and driving-shaft therefor provided with bevel-gearing, of a bearing-block having bearings for the said shaft, said bearing-block being slotted and adapted to engage the grooves of the locking-plates, and screws passing through the slots and into the hopper, substantially as described.

2. In a grain-drill, the combination, with a hopper having grooved locking-plates secured to its under side, of a distributor-chest and a driving-shaft therefor provided with a bevel-gearing, a bearing-block provided with bearings for said shaft and having slotted legs provided with ribs to engage the grooves of the locking-plates, and fastening-screws passing through said slots into the hopper, substantially as described.

3. In a grain-drill, the combination, with a hopper, of locking-plates having grooves on their under sides and provided with pins to enter the hopper and an intermediate aperture, a distributor-chest and driving-shaft provided with bevel-gearing, a bearing-block having bearings for said shaft and having slotted legs provided with ribs to engage the grooves of the locking-plates, and fastening-screws passing through the slots and through the apertures in the locking-plates into the hopper, substantially as described.

700,282. PORTABLE INHALING APPARATUS. JEAN PLANCHET, Lyons, and Louis BOUTHERELAY, Paris, France. Filed Mar. 18, 1902. Serial No. 98,290. (No model.)

Claim.—A portable inhaling apparatus specially adapted for diminishing the effects of sea-sickness, consisting of a steel vessel containing pure oxygen under pressure and provided with a tap *b* for filling and closing it, each tap being formed in such a way as to be only capable of being opened or closed by means of a special key, an expander *c* connected with a branch of the tap *b* for regulating the pressure of the escaping gas, and provided with a handle or key *f* easily accessible to the person using the apparatus, and a flexible tube *d* having at its free end a mask *e* adapted to fit over the nose and mouth of the patient, substantially as described.

700,282.

700,283. BERTH GUARD AND LADDER. JAMES FLANN, Cincinnati, Ohio. Filed Feb. 3, 1902. Serial No. 92,671. (No model.)

Claim.—1. In a berth guard and ladder, the combination substantially as set forth, of an upper berth, vertical postions at the head and foot of the berth, provided with attaching devices, a certain-roll above the upper berth, a ladder provided with hooks at its ends to engage said attaching devices when the ladder is disposed horizontally, fastenings at the front edge of the berth to engage the ladder when disposed vertically, a resilient band near each end of the ladder taking about the certain-roll when the ladder is disposed above the upper berth, rolls for the ladder, openings in a rail for each band, with a connection *E* of the rail between the openings supporting the ladder from the band, a recess in the rail for each band permitting the loops of the bands to be slipped within the rail when the ladder is so disposed horizontally at the upper berth or vertically as stated, and also arranged for having the bands slipped outwardly about the certain-roll for supporting the ladder above the upper berth substantially as described.

2. In a berth guard and ladder, the combination substantially as set forth, of an upper berth, a certain-roll above the same, the hollow ladder-ladder-rails *H*, the holes *P*, *Q*, and connecting-piece *R* near each end of the ladder-rail, the thimbles *S* taking into the holes and protecting the leather, and the resilient bands *M* *N* taking about the certain-roll and connecting-piece *R* and into the hollow rails through said holes *P*, *Q*, each band having a hook *N* and a hole *O*, constructed and arranged for slipping the loops of the bands within the hollow rail and for opening the band and slipping the same about the certain-roll above the upper berth and thereby fastening the ladder thereto.

independent of the said rail-chest, said stiffening-bars bolted together at their middles and secured to the overreaching galvanized ends of the said rail-chest, substantially as described.

700,284. POST. LEONARD A. PRATT, Bay City, Mich. Filed Nov. 8, 1901. Serial No. 91,664. (No model.)

Claim.—1. In a device of the kind described, a wire bent back upon itself to form two members one of which is crimped and the other provided at intervals with loops formed by twisting the wire, for the purpose set forth.

2. In a device of the kind described, a wire bent back upon itself to form two members one of which is crimped throughout its length and the other provided at intervals with loops formed by twisting the wire, for the purpose set forth.

3. In a cement fence-post, reinforcing means comprising in combination a crimped wire extending longitudinally parallel with one side of the post and embedded therein; and a substantially straight member embedded in and extending parallel with the opposite side of the post, said second member being formed of wire bent at intervals to form loops which extend outside the surface of the post, substantially as and for the purpose set forth.

700,285. SHUTTER-PARTNER. GEORGE F. RAIN, Bryerton, Pa. Filed Aug. 9, 1901. Serial No. 71,465. (No model.)

Claim.—In a window-shutter fastener, the combination of a bracket, *2*, secured to the window-sill, said bracket having depressed ends *3*, and a raised central portion *4*, and an integral step *13*; and an unbalanced lever *5* pivotally mounted between the portions *4* and *5* of the bracket formed of a single flat metallic strip having a straight inner end, *2*, a portion *12*, beyond the pivot curved upwardly in the direction of its width, and an outer end portion, *11*, downwardly inclined in a plane transverse to the width of the lever, said lever being arranged with its straight portion extending to substantially the middle of the window below the plane of movement of the shutter, and its inclined portion normally intercepting the plane of movement of the lower edge of the shutter at a point beyond the sill, whereby it operates to automatically hold the shutter in open position; substantially as described.

700,286. HARVESTER-HEEL. CHARLES A. A. RAIN, Chicago, Ill., assignor to Deering Harvester Company, Chicago, Ill. Filed Jan. 6, 1902. Serial No. 93,760. (No model.)

Claim.—In a harvester-heel, a sheet having radial arms, radial-arms secured to said arms as: extending grainward beyond the said radial arms, a series of stiffening-bars radiating from a common center and wholly

700,287. COMBINED FOLDING WARDROBE AND DRESSER. HENRY J. RAINBOLD, Canton, Mo. Filed Aug. 24, 1901. Serial No. 73,126. (No model.)

Claim.—A combined wardrobe and dresser comprising a casing forming the dresser and one side wall of the wardrobe, a section *12* forming the other side wall of the wardrobe, a top and a bottom each formed of a plurality of sections hinged together and to the side walls and adapted to fold inwardly upon themselves, a back formed of hinged sections adapted to fold outwardly and backwardly against the said casing, and a front formed of two doors one of which is hinged to the said casing and adapted to fold against the front thereof, and the other of which is hinged to the section *12* and folds against the outside thereof.

700,288. DELIVERY MECHANISM. GEORGE F. REAR, New York, N. Y., assignor to Robert Hoe, New York, N. Y. Filed June 1, 1901. Serial No. 92,723. (No model.)

Claim.—1. The combination with sheet-advancing means, of a plurality of deliveries, a switch, and means for setting the switch so as to cause a plurality of sheets to be directed in succession to one delivery and then a plurality of sheets in succession to another delivery, substantially as described.

2. The combination with sheet-advancing means, of a plurality of deliveries, a switch, and means for automatically setting the switch so as to cause a plurality of sheets to be directed in succession to one delivery and then a plurality of sheets in succession to another delivery, substantially as described.

the sheet from the cylinder when communication between the channel and the chamber has been interrupted, substantially as described.

16. The combination with a rotating cylinder having a station-ary channel, of a stationary part having an air-chamber with which the channel communicates, means for interrupting the communication between the channel and chamber, and means acting upon the sheet between its ends to throw it off the cylinder when communication between the channel and the chamber has been interrupted, substantially as described.

17. The combination with a rotating cylinder having a station-ary channel, of a stationary part having an air-chamber with which the channel communicates, means for interrupting the communication between the channel and chamber, and means acting upon the forward edge of the sheet and means acting upon the sheet between its ends to remove it from the cylinder when communication between the channel and the chamber has been interrupted, substantially as described.

18. The combination with a rotating cylinder having a plurality of station-ary channels near its periphery, of a stationary head having an air-chamber therein with which the channels communicate, means for interrupting the communication between the channels and the air-chamber, arms carried by the cylinder and arranged to operate upon the sheet when communication between the air-chamber and station-ary channels is interrupted, and a stationary cam for throwing the arms into operation, substantially as described.

19. The combination with a rotating cylinder having a station-ary channel therein, of a stationary cylinder-head having an air-chamber with which the channel communicates, a block mounted in the head and arranged to close the station-ary channel, and an adjusting and locking pin extending through the slot and serving to position the block, substantially as described.

20. The combination with a rotating cylinder having a plurality of station-ary channels arranged near its periphery, of a head having a circular air-chamber with which the channels communicate, and an arc-shaped block located in the chamber and serving to close the channels successively as they pass it, substantially as described.

21. The combination with a rotating cylinder having a plurality of station-ary channels arranged near its periphery, of a head having a circular air-chamber with which the channels communicate, an arc-shaped block located in the chamber and serving to close the channels successively as they pass it, and means for adjusting the block, substantially as described.

22. The combination with a rotating cylinder having a plurality of station-ary channels arranged near its periphery, of a head having a circular air-chamber with which the channels communicate, an arc-shaped block located in the chamber and serving to close the channels successively as they pass it, and a pin-and-dot connection for adjusting the block and locking it in position, substantially as described.

23. The combination with a pair of cutting-cylinders, one of said cylinders having a plurality of station-ary channels, of a stationary head provided with an air-chamber with which the channels communicate, means for interrupting the communication between the chamber and the channels, a sheet-receiver, a stripper acting upon the forward edge of the sheet, and pivoted delivery-arm, said arm and stripper operating to deliver the sheet to the sheet-receiver, substantially as described.

24. The combination with a pair of cutting-cylinders, one of which is provided with a plurality of station-ary channels, of a stationary head having an air-chamber with which the channels communicate, an adjustable block located in said chamber and serving to interrupt the communication between the chamber and the channels, a sheet-receiver, a stripper acting upon the forward edge of the sheet, and pivoted delivery-arm, said arm and stripper operating to deliver the sheet to the sheet-receiver, substantially as described.

25. The combination with a pair of cutting-cylinders, one of which is provided with a plurality of station-ary channels, of a stationary head having a circular air-chamber with which the channels communicate, means for interrupting the communication between the chamber and the channels, a sheet-receiver, a stripper acting upon the forward edge of the sheet, and pivoted delivery-arm, said arm and stripper operating to deliver the sheet to the sheet-receiver, substantially as described.

26. The combination with a pair of cutting-cylinders, one of which is provided with a plurality of station-ary channels, of a stationary head having a circular air-chamber with which the channels communicate, adjustable means for interrupting the communication between the chamber and the channels, a sheet-receiver, a stripper acting upon the forward edge of the sheet, and pivoted delivery-arm, said arm and stripper operating to deliver the sheet to the sheet-receiver, substantially as described.

27. The combination with a pair of cutting-cylinders, one of which is provided with a plurality of station-ary channels, of a stationary head having a circular air-chamber with which the channels communicate, an adjustable block for interrupting the communication between the chamber and the channels, a sheet-receiver, a stripper acting upon the forward edge

of the sheet, and pivoted delivery-arm, said arm and stripper operating to deliver the sheet to the sheet-receiver, substantially as described.

28. The combination with a pair of cutting-cylinders, one of which is provided with a plurality of station-ary channels near its periphery, of a stationary head having a circular air-chamber with which the channels communicate, an adjustable block for interrupting the communication between the chamber and the channels, a sheet-receiver, a stripper acting upon the forward edge of the sheet, and pivoted delivery-arm, said arm and stripper operating to deliver the sheet to the sheet-receiver, substantially as described.

700,940. HUGHES PATENT SYSTEM. LOUIS HUGHES, London, Eng. Filed July 24, 1891. Serial No. 99,612. (No model.)

Claim.—1. In a signal system, a signal-controlling wheel, another wheel having a movement into and out of operative connection with the first-named wheel, an electric device for causing the movement of said second-named wheel, an electric circuit in which the electric device is arranged, and a circuit-closer therefor, substantially as specified.

2. In a block-signal system, a semaphore, a wheel with which the semaphore connects, ratchet-teeth on said wheel, a shaft on which the ratchet-teeth are mounted, an electric device for causing the movement of said ratchet-wheel to engage the teeth of the first-named wheel, an electric circuit in which said electric device is arranged, and a circuit-closer therefor, substantially as specified.

3. In a block-signal device, a semaphore, a wheel for operating said semaphore, the said wheel being provided with a notch in its periphery, ratchet-teeth on opposite sides of said wheel, a shaft on which the wheel is mounted, ratchet-wheels mounted to rotate on said shaft and also having a longitudinal movement thereof, the said ratchet-wheels being at opposite sides of the first-named wheel, and adapted to engage with the ratchet-teeth thereof, solenoids, arms for said solenoids, connections between said arms and the ratchet-wheels, and electric circuits in which the solenoids are arranged, and circuit-closers operated by a car for closing the circuits, substantially as specified.

4. In an electrical-controlled block-signal system, signal device at the ends of the block, and electric motors for causing movement of said signal in one direction, an electric circuit in which said motors are arranged, and circuit-closers at each end of the block, each circuit-closer consisting of a part adapted to be engaged by a flange of a car-wheel, a contact movable with said part, and a fixed contact with which the first-named contact is designed to engage, substantially as specified.

700,941. INTERNAL-COMPRESSION ENGINE. WILLIAM J. BARN, Portland, Ind. Filed Dec. 26, 1891. Serial No. 97,898. (No model.)

Claim.—In a four-cycle explosion-engine, the combination of a working cylinder, a support for the cylinder, a piston to the cylinder, means

for sliding the cylinder upon its support relatively to the piston, a crank-shaft carried by the support, means for operatively connecting the piston with the crank-shaft, a valve to admit fuel to the cylinder, a cam graduated in the direction of its axis of rotation for operating the valve, means for operatively connecting one of these members with the cylinder so that movement of the cylinder causes different portions of the cam to co-operate with the valve, means for operatively connecting the cam with the crank-shaft, and means for maintaining this operative connection when the cylinder is moved upon its support, substantially as and for the purpose set forth.

700,942. LOCK. OWY T. ROBERTS, Orlando Beach, Cal. Filed Jan. 13, 1898. Serial No. 99,641. (No model.)

Claim.—1. In a lock, a plurality of interchangeable dogs having notches, a bolt-controlling latch adapted to enter the same, and means for independently operating said dogs to move them into locking and unlatching positions, said dogs being removably supported by said operating means.

2. In a lock, a plurality of removable combination-dogs having notches, a bolt-controlling latch adapted to enter the same and means for independently moving said dogs to locking and unlatching positions.

3. A combination-dog comprising a reversible polygonal plate having in each of its edges an unlatching-notch, and a carrier in which said dog may be adjusted to prevent any one of the notches in alignment with the bolt-controlling means.

4. A combination-dog comprising a reversible polygonal plate having in each of its edges a single notch arranged in such relation that a notch representing any desired numeral may be adjusted for co-operation with the bolt-controlling mechanism, and mechanism for supporting and adjusting said plate.

5. In a lock, a plurality of combination-dogs, carrying-frames therefor, finger-pieces secured to each of said frames, and means for holding said frames in any position to which they may be adjusted.

6. In a lock, a plurality of combination-dogs, carrying-frames therefor, finger-pieces secured to each of said frames, guiding-plates having shouldered slots, and pins carried by the frames and adapted to said slots.

7. In a lock, a plurality of combination-dogs, bolt-controlling mechanism adapted to co-operate therewith, a series of carrying-frames for said dogs, finger-pieces and pins carried by said frames, and guiding-plates having sliding slots for the reception of said pins.

8. In a lock, a plurality of combination-dogs, bolt-controlling mechanism adapted to co-operate therewith, carrying-frames for said dogs, finger-pieces and pins carried by said frames and guiding-plates having slots for the reception of said pins, each of said slots being arranged to form a series of seating-recesses for the pins, substantially as specified.

9. In a lock, the combination of the lock-casing, bolt-controlling mechanism arranged therein, a bolt, a removable casing extending within the main casing, means for locking said removable casing within the lock-casing when the bolt is in locking position, a series of combination-dogs guided by said removable casing and co-operating with the bolt-controlling mechanism, and means for operating said dogs.

10. In a lock, the combination of the lock-casing, bolt-controlling mechanism arranged therein, a bolt, a removable casing extending within the main casing, means for locking said removable casing within the lock-casing when the bolt is in locking position, a plurality of combination-dogs guided by said removable casing and co-operating with the bolt-controlling mechanism, carrying-frames carried by the removable casing and supporting said dogs, slotted guiding-plates arranged above and removable with the removable casing, and finger-pieces secured to the carrying-frames, said carrying-frames having pins for engagement in the slots of the guiding-plates.

11. In a lock, the combination of the lock-casing, a bolt and bolt-controlling mechanism arranged therein, a removable casing carried by the lock-casing, a series of partitions arranged in said cylinder and having sliding notches for the reception of an element of the bolt-controlling mechanism, combination-dogs arranged within the spaces between the partitions, an independent carrying-frame for each of said dogs, finger-pieces carried by said frames, projecting pins extending from said frames, slotted guiding-plates arranged on the upper portion of the removable casing, the pins being adapted to enter said slots and to be locked therein in an adjusted position.

12. In a lock, the combination of the lock-casing, a partition therein dividing said lock-casing into two compartments, a bolt and bolt-controlling mechanism disposed in one of said compartments, a removable casing having a projecting lug or boss, a locking-finger carried by the bolt for engagement therewith, a series of locking-dogs carried by the removable casing and means for independently adjusting said dogs, substantially as specified.

13. In a lock, the combination with a bolt, of means for effecting the longitudinal movement of the same, a locking-arm adapted to engage with and hold the bolt at both extremes of movement, a latch secured to and movable with the locking-arm, a combination-controlled device for permitting the movement of the latch and arm to unlatching position, and means controlled by the bolt for moving said latch out of contact with the combination-controlled device when the bolt is moved to locked and unlatched position.

14. In a lock, the combination with a manually-operated bolt, of a combination device comprising a series of movable elements each having a notch, a latch adapted to move into the series of notches when the latter are in alignment, a locking-arm operably controlled by the latch for locking said bolt at both extremes of movement, and means controlled by the bolt and its connected parts for moving said latch away from the notches when the bolt is moved to locking or unlatching position.

15. The combination with a manually-operated bolt having a locking-disk, of a combination device comprising a series of movable elements each having a notch, a pivoted latch independent of the bolt and adapted to move into the series of notches when the latter are in alignment, a locking-arm operatively connected to the latch and movable therewith to unlock the bolt, and an engaging finger carried by said bolt and adapted to engage with the latch to move the locking-arm into engagement with the locking-disk of said bolt, substantially as specified.

16. In a lock, the combination with a movable bolt having a pair of locking slots or notches, a locking-arm adapted to engage therewith, a combination device comprising a series of movable elements each having a notch, a pivoted latch carrying the locking-arm and adapted to move into the series of notches when the latter are in alignment, a pivoted lever connected to the bolt, and a link connecting said lever to the latch and adapted to move the latter from the notches and to force the locking-arm into engagement with the bolt when the latter is moved to unlatching position.

17. In a lock, the combination with a movable bolt having a pair of locking slots or notches, a locking-arm adapted to engage therewith, a combination device comprising a series of movable elements each having a notch, a pivoted latch carrying the locking-arm and adapted to

move into the series of notches when the latter are in alignment, a spring adapted to operate on said latch, a pivoted lever connected to the bolt, a secondary lever connected to and movable with said pivoted lever, a U-shaped arm extending from the secondary lever to a point outside the lock-casing, a finger-piece arranged at the end of said arm, holding-legs for said finger-piece, a link connecting the pivoted lever to the latch and adapted to move the same from the notches and to force the locking-arm into engagement with the bolt when the latter is moved to unlatching position, and a finger carried by the bolt and also adapted to operate on said pivoted latch, substantially as specified.

18. In a lock the combination of the lock-casing, a bolt and bolt-operating mechanism contained therein, a removable casing carried by the lock-casing and containing a combination device adapted to cooperate with the bolt-operating mechanism, legs formed in the adjacent faces of the removable casing and lock-casing, and a locking arm or finger carried by the bolt and adapted to pass between said legs.

19. In a device of the class specified, a grooved keeper, a bolt adapted thereto, means for operating said bolt, the engaging end of the bolt being provided with a head or tip of a width less than the width of the grooves of the keeper.

20. In a device of the class specified, a stationary conical member having a keeper at its outer end, a lock-casing carrying said member, a bolt adapted to the casing, means for moving the bolt, a movable semi-circular member pivoted to the lock-casing and in engagement with the bolt, the opposite end of said movable member being adapted to engage in the keeper of the stationary member.

700,248. ROTARY EXPLOSIVE-ENGINE. SAMUEL S. ROSS, Amherst City, Cal. Filed Mar. 20, 1902. Serial No. 700,700. (No model.)

Claim.—The herein-described combined explosive-engine comprising the cylinder, the rotary piston arranged therein, and fixed on a shaft, the passages 12 communicating with the interior of the cylinder at opposite sides of the piston, the exhaust-passages 64, the passages 18; the said passages 12, 64, and 18, intersecting at common points, the passage 16, the supply-passages 63, for gas, the cut-off valve 17 interposed between the passages 63 and 16, and having a crank on its stem, the explosion-chamber 51, the hollow rocking valve 19 and communicating at passage 16 and the lower end of the passages 12, 18 and 64 and coupling between the adjacent ends of the passages 12, 18 and 64 and coupling the points of intersection thereof, the eccentric fixed on the piston-shaft, the strap surrounding said eccentric and adjustably connected to the crank on the stem of the valve 17, the lever 57 connected with the rocking valve 52, and suitable means for igniting explosive mixture in the chamber 51, all substantially as specified.

700,244. PROCESS OF PRODUCING ALLOYS OR COMPOUNDS OF COPPER AND TITANIUM. ALBERT J. ROSS, New York, N. Y., assignor of one-half to James MacLaughlin, Tarrytown, N. Y. Filed Dec. 10, 1900. Serial No. 20,251. (No specimens.)

Claim.—1. The process of producing alloys of metals assembled in the metallic state with metals in oxygenated state which consists in providing a bath of molten reducing metal the heat of the formation of whose acid is at a given temperature greater than that of the acid oxygenated metal; introducing into said bath the said metals assembled in the metallic state and reducing them therein to a molten condition; introducing into said bath the said metals in oxygenated state, and developing in the charge a temperature sufficiently high to lower the requisite reaction between said reducing metal and the oxygen of the oxygenated metal leaving the liquid metallic residuum of the latter to become alloyed with the liquid metallic which were introduced in the metallic state, substantially as and for the purposes described.

2. The process of producing alloys of metals assembled in the metallic state with metals in oxygenated state, which consists in introducing into a bath of aluminum and of molten metals in the metallic state molten together the oxygenated metal and then developing in the charge a temperature sufficiently high to insure the requisite reaction between the molten aluminum and the oxygen of said metals in the oxygenated state leaving the metallic residuum of said last-mentioned metals to become alloyed with the said liquid metallic which was introduced in its metallic state into the charge other than aluminum, while the latter combines with the oxygen of said oxygenated metals and as an aluminum slag containing also other impurities of the charge is separated from the metallic alloy obtained, substantially as and for the purposes described.

3. The process of producing an alloy or compound of copper and titanium which consists in introducing into a bath of aluminum and copper molten together, titanium and then developing in the charge a temperature sufficiently high to insure the requisite reaction between the said molten aluminum and the oxygen of the titanium acid leaving the molten titanium to become alloyed with the molten copper while the aluminum combines with the oxygen of the said titanium acid and as an aluminum slag containing also other impurities of the charge is separated from the said alloy of copper and titanium, substantially as and for the purposes described.

700,245. TRAP-NEST. WILLIAM SMITH, Chicago, Ill. Filed Jan. 20, 1902. Serial No. 20,250. (No model.)

Claim.—1. In a device of the character described, in combination, a nest-compartment, a movable nest therein, a door closing the entrance to the nest-compartment, connection between the nest and the door whereby movement of one will actuate the other, and means controlled by the egg deposited in the nest for holding the nest when depressed from rising.

2. In a device of the character described, in combination, a nest-compartment, a vertically-movable nest therein, a door, connection between the door and the nest, a movable pocket in the bottom of the nest, means actuated by the pocket for holding the nest when depressed from rising, an indicator, and means also actuated by the pocket for operating the indicator.

3. In a device of the character described, in combination, a nest-compartment, a vertically-movable nest therein, a door closing the entrance to the compartment, connection between the door and the nest whereby movement of one will actuate the other, a movable pocket in the bottom

of the nest, a detent, and an arm actuated by the movable pocket for engaging the detent to hold the nest when depressed from rising.

4. In a device of the character described, in combination, a nest-compartment, a vertically-movable nest therein, a door closing the entrance to the compartment, a lever connection between the nest and the door whereby movement of one will actuate the other, a movable pocket in the bottom of the nest, a counterbalance-lever to which the pocket is pivoted, a pivoted arm, connection between the arm and the pocket, and a detent engaged by the arm to hold the nest when depressed from rising.

5. In a device of the character described, in combination, a nest-compartment, a vertically-movable nest therein, a door adapted to close the entrance to the compartment, a lever connected at one end to the door and having its opposite end extending in the path of the nest, a movable pocket in the bottom of the nest, a pivoted lever connected to the pocket, a counterbalance-weight on the lever, a pivoted loop actuated by the pocket, an indicator hinged to the wall of the nest-compartment, a lever actuated by the loop for operating the indicator, and a detent engaged by the loop for holding the nest when depressed from rising.

6. In a device of the character described, in combination, a nest-compartment, a vertically-movable nest therein, a door closing the entrance to the nest-compartment, connection between the nest and the door whereby movement of one will actuate the other, means for holding the nest when depressed from rising, an alarm, an electric circuit therefor, and means controlled by the movable nest for closing the circuit.

7. In a device of the character described, in combination, a nest-compartment, a vertically-movable nest therein, a door closing the entrance to the nest-compartment, connection between the nest and the door whereby movement of one will actuate the other, means for holding the nest when depressed from rising, a battery, a contact-plate, connection between the battery and the plate, connection between the battery and the means for holding the nest whereby the circuit is closed when the nest is held in its lowered position, and an alarm in the connection.

8. In a device of the character described, in combination, a nest-compartment, a vertically-movable nest therein, a door closing the entrance to the nest-compartment, connection between the nest and the door whereby movement of one will actuate the other, a movable pocket in the bottom of the nest, means actuated by the movable pocket for holding the nest when depressed from rising, an alarm, an electric circuit therefor, means controlled by the movable pocket for closing the circuit, and an indicator controlled by the means actuated by the movable pocket.

9. In a device of the character described, in combination, a nest-compartment, a vertically-movable nest therein, a door closing the entrance to the nest-compartment, connection between the nest and the door whereby movement of one will actuate the other, a movable pocket in the bottom of the nest, a counterbalance-lever to which the pocket is pivoted, a pivoted arm, connection between the arm and the pocket, an indicator hinged to the wall of the compartment, a lever actuated by the arm for operating the indicator, a detent engaged by the arm for holding the nest when depressed from rising, a battery, a plate located at the side of the detent, connection between the battery and the plate, connection between the battery and the pivoted arm, and an alarm in one of said connections, the parts being so disposed that when the arm engages the detent the circuit will be closed and the alarm rung.

10. In a trap-nest, in combination, a nest-compartment, a movable nest therein, a door closing the entrance to the nest-compartment, connection between the nest and the door whereby movement of one will actuate the other, a movable pocket in the nest, and means controlled by the pocket for holding the nest when moved from returning to its original position.

11. In a trap-nest, in combination, a nest-compartment, a movable nest therein, a door for the nest-compartment, means actuated by the nest for closing the door, and means controlled by the egg deposited in the nest for holding the nest when moved from returning to its original position.

12. In a trap-nest, in combination, a nest-compartment, a vertically-movable nest therein, a door for the nest-compartment, means actuated by the nest for closing the door, means actuated by the egg deposited in the nest for holding the nest when depressed from rising, an indicator, and means controlled by the movable nest for operating the indicator.

13. In a device of the character described, in combination, a vertically-movable nest having an independently-movable egg-pocket, yielding supports for each member, an electric signal, a switch in the circuit thereof, and means actuated by the independent movement of the said members for closing the circuit.

14. In a trap-nest, in combination, a nest-compartment, a movable nest therein, a door for the nest-compartment, means actuated by the nest for closing the door, an indicator, an alarm, and means controlled by the movable nest for operating the indicator and for closing the circuit to actuate the alarm.

15. In a device of the character described, in combination, a nest-

compartment, a nest therein and having a movable bottom, an alarm, an electric circuit, and a lever controlled by the movable bottom and for closing the circuit to actuate the alarm.

700,248. FLEXIBLE COUPLING. CHARLES L. SHULLS and SAMUEL A. SHULLS, Chicago, Ill. Filed Sept. 14, 1891. Serial No. 21,022. (No model.)

Claim.—In a flexible coupling, a divided shaft, a disk on each of the ends of said divided shaft, said disks facing each other, two lugs projecting at a right angle from the face of each disk, said facing disks connected by means of two curved bars having an extremity-arm on each end, and each arm bent at an angle of thirty-five degrees and engaging a lug on said facing disks, substantially as specified.

700,247. ROTARY FLOW. JOHN SCOTT, Edinburgh, Scotland. Filed Jan. 7, 1902. Serial No. 21,774. (No model.)

Claim.—1. A device of the class described comprising a disk having a helically-shaped blade projecting from one face thereof and tapered in the direction of its outer end.

2. A device of the class described comprising a disk having a helically-shaped blade projecting from one face thereof and continuously tapered in the direction of its outer end.

3. A device of the class described comprising a circular supporting-disk having a beveled cutting edge and a blade projecting laterally therefrom, said blade being bent into helical form of changing radius.

4. A device of the class described comprising a supporting-disk having a beveled cutting edge, said disk having a blade projecting therefrom, said blade being bent to form a helix of gradually-decreasing radius.

5. A device of the class described comprising a supporting-disk having a beveled cutting edge, said disk having a tapered blade projecting therefrom, said blade being bent to form a helix of gradually-decreasing radius.

700,248. WATER-TUBE BOILER. JAMES A. SCOTT, Yonkers, N. Y. Filed June 12, 1901. Serial No. 64,354. (No model.)

Claim.—1. A water-tube boiler having a group of tubes extending upwardly to the steam-drum and separated into two divisions, and having a tight, hollow casing between said divisions, said casing being closed at its end and extending from one end of the outer boiler-casing the major part of the distance to the other end of the boiler-casing, whereby the gases are compelled to flow from one end to the other in one section or division of the group of tubes, and in the opposite direction in the other division thereof, substantially as set forth.

2. A water-tube boiler having its groups of tubes subdivided throughout a part of their depth by spaces to afford access for cleaning and the like, and casings within said spaces which bar the entrance thereto of the gases, whereby the latter are barred from direct passage through the mass of tubes, substantially as set forth.

3. A water-tube boiler having two outer water-drums, a central water-drum, grates between the outer and central water-drums, a steam-drum above and over the central water-drum, heat water-tubes connecting the outer water-drums with the steam-drum, upright water-tubes connecting the central water-drum with the steam-drum, and casings subdividing the groups of tubes for the major portion of the depth of the generator to compel the gases, on their way to the stack, to circulate in opposite directions through said subdivisions, substantially as set forth.

4. A water-tube boiler having two outer water-drums, a central water-drum, grates between the outer and central water-drums, a steam-drum above and over the central water-drum, water-tubes connecting the outer water-drums with the steam-drum, water-tubes connecting the central water-

drawn with the steam-drum, the furnace-tubes forming a wall or crown-sheet for the major part of the length of the boiler compelling the gases to enter the clusters of tubes at one end and pass among the tubes to the other end into the uptake, and a casing subdividing the central group and covering the outer groups, said casing being removable to allow access for cleaning the tubes, all combined substantially as set forth.

700,249. APPARATUS FOR MAKING SULFURIC ACID. ANTHONY H. G. SCHILLER, Paris, France. Filed Dec. 20, 1899. Serial No. 59,982. (No model.)

Claim.—An apparatus for manufacturing concentrated sulfuric acid, comprising a vertically-arranged casing formed of suitable bricks, a perforated partition at the bottom part and within said casing, a thick layer of pumice-stone and asbestos supported on said partition, a series of perforated plates, at the top part and, within the casing, layers of spongy platinum on said perforated plates, a mixing-chamber above the latter, a pipe connected to said chamber for the introduction of sulfuric acid thereto, a steam-pipe discharging steam into the chamber, an air-admission aperture through which said steam-pipe extends, means for regulating the quantity of steam admitted into the chamber with the transmitting or receiving apparatus, and means for forcing the mixed gases from said chamber through the various layers contained in the casing, substantially as and for the purpose set forth.

700,250. WIRELESS TELEGRAPHY. HARRY BUCHHEIM, Philadelphia, Pa., assignor to Gustave P. Gehring and American Wireless Telephone and Telegraph Company, Philadelphia, Pa. Filed July 21, 1901. Serial No. 70,250. (No model.)

Claim.—1. In a wireless-telegraph system, the combination in a terminal station, of an aerial conductor, a transmitting instrument, a receiving instrument, an electro-magnetically-operated and spring-retained means connected to the conductor, and a switch to make a circuit, which energizes the said means to connect the transmitting instrument to the aerial conductor, the spring of other means causing the receiving instrument to be connected to the aerial conductor.

2. A terminal station of a wireless-telegraph system, comprising an aerial conductor, a pair of levers insulated from each other and adapted to swing in unison, one being connected to said conductor, means for operating said levers, a transmitting apparatus, a receiving apparatus, and a switch for controlling a circuit to operate said levers to connect the transmitting or the receiving apparatus with the aerial conductor.

3. A terminal station of a wireless-telegraph system comprising an aerial conductor, two independent insulated means adapted to move in unison and having one connected with its aerial conductor, a transmitting apparatus, a receiving apparatus, and means for controlling a circuit to operate said before-mentioned means to connect the transmitting or the receiving apparatus with the aerial conductor.

4. A terminal station of a wireless-telegraph system comprising an aerial conductor, a pair of levers insulated from each other and adapted to swing in unison, one of said levers being connected to the conductor, a transmitting apparatus, a receiving apparatus, and means for controlling a circuit to operate said levers to connect the transmitting or receiving apparatus with the conductor.

5. A terminal station of a wireless-telegraph system comprising an aerial conductor, a pair of pivoted levers connected by insulation, one of said levers being connected to the conductor, a transmitting apparatus, a receiving apparatus, and electro-magnetic means in said circuit operated simultaneously with the solenoid for cutting the receiving-station out when the transmitting-station is being operated.

6. A terminal station for a wireless-telegraph system comprising a single aerial conductor, a transmitting instrument, a receiving instrument, means for connecting either one of said instruments to the conductor, means for throwing into operation said first-mentioned means, and another means in circuit with the first-mentioned means operated when the transmitting instrument is connected with the aerial conductor to cut the receiving instrument out.

7. A terminal station for a wireless-telegraph system comprising an aerial conductor, a transmitting apparatus, a receiving apparatus having a coherer, a relay-circuit and a sounder-circuit, electro-magnetically-operated means for connecting the aerial conductor with the transmitting or receiving apparatus, another electro-magnetically-operated means in the same circuit as the one above mentioned energized when the transmitting apparatus is connected with the conductor for cutting the coherer, relay-circuit and sounder-circuit out, and manually-operated means for causing said electro-magnetically-operated means to be energized.

8. A terminal station of a wireless-telegraph system comprising an aerial conductor and two ground-conductors, a transmitting apparatus, a receiving apparatus, a pair of levers for connecting the transmitting ap-

paratus or the receiving apparatus to the aerial conductor, a circuit made when the transmitting apparatus is connected to the aerial conductor, and electro-magnetically-operated means for cutting out the receiving apparatus when the transmitting apparatus is connected with the aerial conductor.

9. A terminal station of a wireless-telegraph system comprising an aerial conductor, a transmitting apparatus, a receiving apparatus, a pair of pivoted levers adapted to be operated to connect the transmitting or receiving apparatus to the aerial conductor, a circuit, a solenoid and a pair of electro-magnets located in said circuit, a switch for connecting said circuit to energize the solenoid to operate the levers and connect the transmitting apparatus with the aerial conductor, and switch-points operated simultaneously by the electro-magnets to cut out the receiving apparatus.

700,251. LOCK FOR ADJUSTABLE BALL-BEARING COVER. ARTHUR C. SMITH, Milwaukee, Wis., assignor to Automobile and Cycle Parts Company, Cleveland, Ohio, a Corporation of New Jersey. Filed June 10, 1901. Serial No. 69,983. (No model.)

Claim.—The combination of an axle having a longitudinal groove and an adjustable cone secured on said axle and having a plurality of equally-spaced notches, with a locking-washer having an inwardly-extended tongue, which takes into said groove, and an outwardly-extended tongue adapted to engage with one of said notches, the angular distance between said tongues being substantially equal to the angle represented by the following formula: $X = \frac{1}{2} \frac{1}{n}$, substantially as and for the purpose specified.

700,252. PENCE-POST-MAKING MACHINE. GEORGE E. SMITH and FRANK T. BAKER, Athens, Mich. Filed Sept. 6, 1901. Serial No. 74,982. (No model.)

Claim.—1. The combination, in a machine for making penny-posts of plastic material, of a metallic flask and a frame at each end of said flask, a reciprocating plunger guided in said frame at each end of said flask, wheels at each side of said flask and having notches in their peripheries which embrace said flask as described, and means for moving the wheels with a step-by-step movement, whereby the flask is fed along and the ends of the posts are compressed by the plungers while the flask is held by the wheels, substantially as described.

2. The combination of the post-making flask open at both ends, the plungers closing into said flask, wheels at each side of the flask having notches in their rims by which the flask is supported, partly inclined, and carried forward, and clutch-and-pawl mechanism by which the wheels are rotated with a step-by-step movement, substantially as described.

3. In a machine as described, an open-ended flask composed of two hollow metallic sections, a back and rib forming the connection at one side of the sections, and a rib on each part held in place by a grooved band, at the opposite side of the sections, in combination with rotating notched wheels for feeding said flask forward, and plungers for applying and pressure to the sections of the flask, all combined.

4. In a machine for making concrete penny-posts, a hollow sectional flask, open at both ends, and means for holding the flask-sections together, means for feeding the flask and contents forward with a step-by-step movement, and reciprocating plungers at each end of the flask, to enter and compress the material therein, all combined substantially as described.

700,253. CIGARETTE-MAKING MACHINE. FRANK SMITH, New York, N. Y., assignor of one-half to Charles A. Brantley, New York, N. Y. Filed May 12, 1901. Serial No. 69,113. (No model.)

Claim.—1. In a cigarette-making machine, means for forming and compressing the tobacco comprising two complementary members, means for moving both members synchronously toward and away from each other, and means for ejecting the tobacco after it is so formed and compressed and while retained by said members, as set forth.

2. In a cigarette-making machine, a support for the tobacco, means for forming and compressing the tobacco comprising two complementary members mounted on said support, means for moving both members synchronously toward and away from each other transversely of the support, and means for ejecting the tobacco after it is so formed and compressed and while retained by said members, as set forth.

3. In a cigarette-making machine, means for forming and compressing the tobacco, mechanism for actuating the same, means for moving each forming and compressing means downwardly while being actuated by said mechanism, and means for ejecting the tobacco at the termination of the downward movement of each forming and compressing means, as set forth.

4. In a cigarette-making machine, means for forming and compressing the tobacco comprising two complementary members, means for transversely moving both members synchronously toward and away from each other, means for moving each forming and compressing means downwardly simultaneously with their transverse movement toward each other, and means for ejecting the tobacco at the termination of the downward movement of each member, substantially as set forth.

5. In a cigarette-making machine, a member comprising complementary forming and compressing jaws, means for synchronously moving both jaws laterally toward and away from each other, and means for ejecting the tobacco from the jaws after it is so formed and compressed and while retained by the jaws.

6. In a cigarette-making machine, a member comprising forming and compressing jaws normally open, means connected to each jaw for actuating them laterally, means for moving both jaws vertically or at right angles to their lateral movements, said actuating means operating on the jaws during each vertical movement, and means for ejecting the tobacco from the jaws at the termination of the first vertical movement.

7. In a cigarette-making machine, a member comprising forming and compressing jaws normally open, toggle-arms connected to each jaw, means for moving both jaws vertically, said toggle-arms actuating the jaws during each vertical movement, and means for ejecting the tobacco from the jaws at the termination of the first vertical movement.

8. In a cigarette-making machine, a member comprising a support, means for moving the same vertically, two forming and compressing jaws movable with said support and also laterally toward and away from each other, and toggle-arms acting on each jaw for effecting the lateral movements thereof during the vertical movements of the support, as set forth.

9. In a cigarette-making machine, a member comprising forming and compressing jaws normally open, toggle-arms connected to each jaw, a bed-plate on which the jaws are mounted and on which they are designed to move laterally, means for raising and lowering said bed-plate, said toggle-arms actuating the jaws during each movement of the bed-plate, and means for ejecting the tobacco from the jaws at the termination of the lowering movement of the bed-plate, as set forth.

10. In a cigarette-making machine, a member comprising two jaws normally open, a casing wherein the latter are located, means for moving

the jaws vertically, means for moving the jaws toward and away from each other during each vertical movement, an ejector, and means for projecting the mass through the casing and jaws when the latter are at the end of their downward vertical movement, as and for the purpose set forth.

11. In a cigarette-making machine, a molder comprising forming and compressing jaws, means for moving both jaws laterally first toward each other and then slightly apart, and means for ejecting the tobacco while the jaws are in the last-mentioned position.

12. In a cigarette-making machine, a molder comprising forming and compressing jaws, toggle-arms secured to each jaw, means for moving the jaws vertically so that the toggle-arms will move them laterally first toward each other and then slightly apart, and means for ejecting the tobacco while the jaws are in the last-mentioned position.

13. In a cigarette-making machine, a molder comprising forming and compressing jaws, means for moving the jaws laterally, first toward each other, and then slightly apart, the ejector conforming in cross-section to the space between the jaws when in the last-mentioned position, and means for moving such ejector longitudinally between the jaws, substantially as set forth.

14. In a cigarette-making machine, a molder comprising forming and compressing jaws having knife-like edges, the edge of one jaw being arranged to overlap the edge of the other, and means for moving said jaws laterally toward and away from each other, substantially as set forth.

15. The combination with the box having openings in its ends, the bed-plate, and the two side jaws, of means for lowering and raising said bed-plate and jaws, the toggle-arms secured to said jaws and to the box for moving the former laterally during their vertical movements, the ejector conforming in cross-section to the space between the jaws when lowered and also to the openings in the box, and means for moving the ejector longitudinally, substantially as set forth.

16. In a cigarette-making machine, flexible guides for the tobacco, jaws beneath and to which each guide are connected, said jaws being normally open, and means for moving the jaws laterally toward and away from each other, as set forth.

17. In a cigarette-making machine, guides for the tobacco, jaws beneath each guide, means for moving the jaws and the guides vertically, means for moving the jaws laterally during each vertical movement, said jaws being opened to receive the tobacco when at the limit of their upward movement, and means with which said jaws are brought in line when at the limit of their downward movement, for ejecting the tobacco therefrom, as set forth.

18. The combination with the box, the bed-plate and the forming and compressing jaws mounted on the latter, of means for synchronously moving said jaws laterally, the flexible plates secured at their inner edges to said jaws, and the guides for said plates at the sides of the box, substantially as set forth.

19. In a cigarette-making machine, the combination with the molder, of the outlet-spout, having a bearing for a paper tube, a lever having a flexible portion, a spring for holding said portion normally in engagement with said spout for retaining a paper tube thereon, an ejector for forcing the tobacco from the molder through the spout, and mechanism for positively disengaging the said flexible portion from the spout, first, as the ejector reaches the limit of its discharge movement, and, second, when the machine is completing the final cycle of its movements, substantially as set forth.

20. The combination with the molder, the spout, and the ejector, of the lever, a spring acting thereon, a flat spring carried by each lever for holding a paper tube on said spout, and mechanism for actuating the ejector and engaging said lever to free said spring from contact with the spout as the ejector reaches the limit of its discharging movement, substantially as set forth.

21. The combination with the bed-plate, and springs normally holding the same raised, of the jaws, means for lowering the bed-plate as against the tension of the springs, said jaws being movable with said bed-plate, toggle-arms connected to said jaws for moving them laterally as they travel with the bed-plate, the ejector-rod, and means for moving the latter longitudinally between the jaws, as set forth.

22. The combination with the table having an opening therein, of the molder located beneath said opening comprising forming and compressing mechanism normally held elevated and open to receive the charge of tobacco, a vertically-movable support for such mechanism, an outlet-spout and ejector located in line beneath the upper or normal level of said mechanism, and means for actuating the ejector when the forming and compressing mechanism is in line therewith, substantially as set forth.

23. The combination with the table having an opening therein, of the molder located beneath said opening comprising forming and compressing mechanism normally open to receive the charge of tobacco, flexible guide-plates secured to each mechanism, means for actuating the latter after the tobacco is received therein, and an ejector and its operating mechanism located wholly beneath the table, substantially as set forth.

24. The combination with the table having an opening therein, and the molder located beneath said opening comprising an inclosure, forming and compressing mechanism therein, flexible guide-plates secured to each mechanism, and means for raising and lowering said mechanism and plates in the formation of the cigarette-core, of an ejector-rod movable longitudinally through said molder on a line beneath the point of discharging said forming and compressing mechanism, and mechanism located wholly beneath the table for first actuating the molder and then the ejector, substantially as set forth.

25. The combination with the molder comprising a vertically-movable support and forming and compressing jaws carried thereby, of a lever for actuating said support, means for moving such jaws during such actuation, a cam for operating said lever, a longitudinally-movable ejector-rod located beneath the normal upper position of the support, an actuating-lever for such ejector-rod, a second cam for operating such lever, a foot-rod, and mechanism actuated thereby for operating said cam, substantially as set forth.

700,254. SCALE. CHARLES S. BRIDGES, Detroit, Mich. assignor of one-half to George H. Paine, Detroit, Mich. Filed May 27, 1901. Re-nued Mar. 17, 1902. Serial No. 30,657. (No model.)

Claim.—1. A scale-bearing comprising a bearing-block, a casing therefor adapted to be engaged therewith by an endwise movement, and a support for said block having a pin or bar extending transversely of and bearing upon said block and adapted to hold said casing and block from endwise displacement in relation to each other.

2. A scale-bearing comprising a transversely-grooved bearing-block, a casing embracing said block and adapted to be in engagement therewith by an endwise movement, said casing having apertures in its sides adapted to register with said groove in the block, and a support embracing said casing and block having a transverse bar or pin for engaging said transverse groove, said bar or pin forming a pivotal bearing for said block.

3. A scale-bearing comprising a transversely-grooved bearing-block, a casing embracing said bearing-block by an endwise movement and having apertures in its sides for registering with said groove, and an imperforate portion opposite the side of said groove; a bifurcated support for embracing the sides of said block and casing and a pin passing through said support and grooves in said block whereby the latter has a pivotal bearing on said pin and whereby said casing is held from endwise movement and forms a retainer for preventing disengagement of said block from said support.

4. A scale-bearing comprising a bifurcated support, an inclosed bearing-block embraced by said support, and a transverse pin or bar in said support forming a pivotal bearing for said block; said block being provided with a transverse groove for engaging with said pin and the casing for said block having apertures in its sides registering with said groove but extending inward beyond the bottom of said groove whereby said pin will have its supporting-bearing upon the block only and will hold said casing from endwise movement.

5. In a scale a stay-rod having a hooked lower end, a bearing-block and a casing therefor, the latter fitting within said hook and a pin for pivotally connecting said casing to said hook adapted to lock said block in engagement with said casing.

700,255. FLOWERS. JOHN L. BULLIVANT, North Carrollton, Minn. Filed Sept. 30, 1901. Serial No. 73,728. (No model.)

Claim.—1. A reversible plowshare comprising two wings substantially triangular in shape, said wings being outwardly in form as seen

angle, the meeting edges of the wings forming the cutting edge of the share, substantially as and for the purpose set forth.

2. A reversible plowshare comprising two flaring wings substantially triangular in shape and provided with points, one of said points having a flange opposite to that of the other, substantially as and for the purpose described.

3. A reversible plowshare comprising two wings substantially triangular in shape, said wings flaring outwardly to form an acute angle, the meeting edges of the wings forming the cutting edge of the share, and oppositely-directed points upon the share, substantially as and for the purpose specified.

4. A reversible plowshare substantially triangular in shape and comprising two outwardly-flaring wings, said wings flaring together at an acute angle and the meeting edges thereof forming the cutting edge of the share, and independently-projecting points substantially connected to the share and one of said points having a flange opposite to that of the other, substantially as and for the purpose set forth.

700,256. FARMER FOR BACKINGS IN PICTURE-FRAMES. JAMES L. TAYLOR, Chicago, Ill. Filed Apr. 1, 1901. Serial No. 30,700. (No model.)

Claim.—1. In a backing-frame for frames, in combination, a body portion adapted to fit within the rear face of the frame; a latch pivotally secured to said body portion, said latch having a point on one side of its pivot, adapted to engage the lower edge of the frame to prevent the removal of the backing from the frame; and a fixed locking projection for holding the latch in engagement with the frame.

2. In a backing-frame for frames, in combination, a body portion adapted to fit within the rear face of the frame; a thumb-latch pivotally secured to said body portion, said latch having a point on one side of its pivot, adapted to engage the lower edge of the frame to prevent the removal of the backing from the frame; a projection upon the back surface of said pivot, adapted to be engaged by the thumb or finger of the operator and a fixed locking projection for holding the latch in engagement with the frame.

3. In a backing-frame for frames, in combination, a body portion adapted to extend across the corner of the frame; and a locking-latch pivotally mounted on said body portion near one end thereof, which latch is provided with a point extending to one side of said pivot, adapted to engage the lower edge of the frame to hold said end of the body portion in position relatively to said frame and prevent the removal of the backing from the frame.

4. In a backing-frame for frames, in combination, a body portion adapted to fit within the rear face of the frame; a latch pivotally mounted on said body portion, said latch having a point extending to one side of said pivot, adapted to engage the lower edge of the frame when said latch is turned upon its pivot, to prevent the removal of said backing; means consisting with said latch for holding the body portion in position relatively to the frame and a fixed locking projection for holding the latch in engagement with the frame.

5. In a backing-frame for frames, in combination, a body portion adapted to extend across the corner of the frame; and a locking-latch pivotally mounted on said body portion near each end thereof, which latches are adapted to engage the frame.

6. In a backing-frame for frames, in combination, a body portion adapted to extend across the corner of the frame; a latch pivotally mounted on said body portion near each end thereof, which latches are adapted to penetrate the substance of the frame when they are turned upon their pivots; and a locking projection for holding the latches in engagement with the frame.

7. In a backing-frame for frames, in combination, a body portion adapted to extend across the corner of the frame; a latch pivotally mounted on said body portion near each end thereof, each of which latches is provided with a point extending outward from said pivot and adapted to penetrate the substance of the frame when the latch is turned upon its pivot; a fixed locking projection for holding each of the latches in engagement with the frame; and a projection extending from one of said latches adapted to be grasped by the operator.

700,257. CHIP-BREAKER FOR WOODWORKING-MACHINES. JOHN R. TUCKER, Cincinnati, Ohio, assignor to J. A. Fay & Ryan Company, Cincinnati, Ohio, a Corporation of West Virginia. Original application filed May 20, 1901. Serial No. 30,413. Divided and this application filed Dec. 20, 1901. Serial No. 37,022. (No model.)

Claim.—1. In a woodworking-machine, the combination with a cutter-head, of a chip-breaker therefor, and a pressure device for the chip-breaker, with means for permitting the sidewise movement of the pressure device transversely of the chip-breaker, substantially as described.

2. In a woodworking-machine, the combination of a chip-breaker, means for permitting the same to swing, a lever for the chip-breaker, a weight for the lever, a spring interposed between the lever and the chip-breaker, and means for permitting the sidewise movement of the lever with relation to the chip-breaker, substantially as described.

3. In a woodworking-machine, the combination of a chip-breaker, a swinging frame therefor, a rod for supporting the swinging frame, means for permitting sliding sidewise of the swinging frame upon the rod, a weighting device for the chip-breaker, with means for permitting the sidewise movement of the weighting device for exerting pressure from the weighting device upon the chip-breaker at different points across the latter, substantially as described.

700,258. SEAL-LOCK. JOHN R. TUCKER, American, Ga. Filed Apr. 13, 1901. Serial No. 30,740. (No model.)

Claim.—1. A lock comprising a pair of oppositely-disposed swinging locking-bars pivoted at their lower adjacent ends to fixed supports, the outer terminal locking-bolts pivotally connected to the outer ends of the bars and extending longitudinally thereof and arranged in alignment with the same when in their engaging position, and operating mechanism pivotally connected with the swinging bars at points between the ends thereof, substantially as described.

2. A lock comprising a pair of oppositely-disposed locking-bars pivoted at their inner ends to fixed supports, the outer terminal locking-bars pivotally connected to the outer ends of the bars and extending longitudinally thereof and arranged in alignment with the same when in their engaging position, a rotatable tumbler, links pivoted to the tumbler and similarly connected to the locking-bars at points between the ends thereof, substantially as described.

3. A lock comprising the upper and lower horizontally-disposed locking-bars provided with linear terminal pivotal supports, the horizontally-disposed outer terminal locking-bars pivoted to and extending longitudinally of the said bars and arranged in alignment with the same when in their engaging position, a central tumbler, links extending from the central tumbler to the locking-bars at points between the ends of the latter, and the vertically-movable arms arranged above the upper locking-bars and pivoted to the same at points between the ends thereof, substantially as described.

4. In a lock, the combination with a keeper, of a spindle, a handle fixed to the spindle and adapted to be oscillated to rotate the same, and a reciprocating locking-bolt mounted on the handle and extending through and arranged to project beyond the spindle and adapted to engage the keeper, whereby the handle is locked, substantially as described.

5. A lock, having a rotatable spindle, a combined stop and bearing-plate having a central opening for the projection therethrough of the spindle, an enlarged recess formed in the outer side of the plate and about the spindle-opening, the marginal wall thereof being provided with a pair of spaced stop-sockets, opposite stop projections upon the plate and corresponding with the notches, and a crank-handle fixedly connected to the projected end of the spindle and movable in an arcuate path limited by the stop projections, and having an endwise-movable locking bar or bolt for engagement with the respective notches or sockets to lock the handle at opposite limits.

6. A lock, having a rotatable spindle, a combined stop and lock-plate, having a spindle-receiving opening, an enlarged recess formed around the opening and in the outer face of the plate, the walls of the recess having a pair of spaced notches or sockets, the outer face of the plate also being provided with a quadrant-shaped recess intersecting the former recess, the opposite walls of the segmental recess forming stop-shoulders corresponding to the notches or sockets, and a handle which is hollow and is fixedly connected to the outer projected end of the spindle, said handle traveling in the segmental recess and limited by the opposite walls thereof, and also provided with an internal endwise-movable locking-bolt, that works through a diametric opening in the spindle and is adapted to take into the respective sockets to lock the handle at opposite limits.

7. In a lock, the combination with a keeper, of an oscillatory handle provided with a tubular portion forming a casing and having a coil-receiving opening and a coil-exposing opening, a reciprocating bolt provided with a coil-carrying chamber, and a sleeve mounted on the handle and connected with and adapted to reciprocate the bolt and provided with openings adapted to register with the openings of the casing, substantially as described.

8. In a lock, the combination with a keeper, of an oscillatory handle, a reciprocating bolt mounted within the handle and carried by the same and adapted to engage the keeper, said bolt being provided with a coil-carrying chamber, and the said handle being provided with coil-receiving and coil-exposing openings, and an automatically-operating locking device arranged to engage the coil when the bolt is in its engaging position, substantially as described.

9. A lock, having a slidable locking-bolt, a casing therefor, a frangible coil carried by the bolt, and a spring-actuated locking device mounted within the casing and constructed to snap automatically into locked engagement with the coil at the forward limit of the bolt, the casing having a coil-receiving opening, and a coil-exposing opening located at the locked limit of the coil.

10. A lock, having a slidable locking-bolt, a casing therefor, the outer end portion of the bolt which is within the casing being reduced, and provided in its inner side with a coil-receiving notch, a plug fitted fixedly within the casing and occupying the space provided by the reduced portion of the bolt, the outer portion of the inner face of the plug having a recess corresponding to the notch in the bolt, a coil-engaging spring-actuated latch mounted within the recess, the inner end portion of the plug having a lateral opening, and a frangible coil carried in the coil-receiving notch of the bolt and movable therewith to a position opposite the opening in the plug at the locked limit of the bolt, the latch being constructed to snap into engagement with the outer end portion of the coil at the locked limit of the bolt, the casing having a coil-receiving opening aligned with the coil-receiving notch of the bolt in the withdrawn limit thereof, and a coil-exposing opening aligned with the similar opening in the plug, to permit of access to the coil for breaking the same.

11. A lock, having a slidable locking-bolt, a casing therefor, a frangible coil carried by the bolt and having an interlocked engagement with the casing at the locked limit of the bolt, the casing having a coil-receiving opening and a coil-exposing opening at the opposite limits of the coil, and a rotatable adjusting-sleeve mounted upon the casing, and operatively connected to the bolt for sliding the latter in opposite directions.

12. A lock, having a slidable locking-bolt, a tubular casing therefor, having opposite coil-receiving and coil-exposing openings, and a longitudinal slot, a frangible coil carried upon the end of the bolt within the casing and adjacent to the openings therein, and a rotatable sleeve mounted exteriorly upon the casing, and having a spiral internal groove or slot, a projection upon the bolt and working in the slot of the casing and in the slot or groove of the sleeve, whereby a rotation of the latter will cause the bolt to move endwise, the sleeve having a coil-receiving opening corresponding to the similar opening in the casing at the withdrawn limit of the bolt, and a coil-exposing opening corresponding to the similar opening of the casing at the locked limit of the bolt.

13. A lock, having a rotatable part, a tubular crank-handle connected thereto, and provided with an internal locking-bolt, a frangible coil carried by the bolt, and a locking device for engaging the coil when the bolt is in its engaging position, substantially as described.

14. A lock, having a rotatable part, a tubular crank-handle connected thereto, an internal slidable locking-bolt within the handle, a frangible coil carried by the bolt and within the handle, and engaging the same and the handle when the bolt is in its engaging position, a rotatable belt-adjusting sleeve mounted externally upon the handle, and having an internal spiral groove or slot, and a projection upon the bolt and received within the groove or slot of the sleeve, the handle having a slot for the slidable reception of the projection, and the sleeve and handle having corresponding coil-receiving openings which are aligned at the withdrawn limit of the bolt, and corresponding coil-exposing openings which are aligned at the locked limit of the bolt.

15. A lock, comprising a casing, an endwise-slidable locking-bolt within the casing and having a coil-receiving notch in one side thereof, the inner side of the handle also having a coil-receiving notch which is aligned with the corresponding notch of the bolt in the locked position thereof, and means for moving the coil laterally from the bolt so as to fit partly in both notches and thereby form an interlocked connection between the bolt and the handle.

16. A lock, comprising a casing, having a coil-exposing opening, the inner side of which is provided with a marginal notch, an endwise-movable bolt within the casing, and having one side provided with a coil-receiving notch that is aligned with the notch and opening of the casing in the locked position of the bolt, and means for moving the coil laterally from the bolt and to fit partly in the notches of the bolt and the casing, thereby to form an interlocked connection between the bolt and the casing.

17. A lock, comprising a casing, having a coil-exposing opening, the inner side of which is provided with a marginal notch, an endwise-movable bolt within the casing, and having one side provided with a coil-receiving notch that is aligned with the notch and opening of the casing in the locked position of the bolt, and means for moving the coil laterally from the bolt and to fit partly in the notches of the bolt and the casing, thereby to form an interlocked connection between the bolt and the casing.

700,259. GAR-DOOR. JOHN R. THOMSON, American. Original application filed Apr. 13, 1901. Serial No. 55,748. Divided and this application filed Aug. 25, 1902. Serial No. 72,363. (No model.)

Claim.—1. The combination of a doorway or frame having a beveled inner marginal portion, a laterally-movable door, and a lock having a slidable frame-engaging door-chilling device, which is constructed for diagonal engagement with the beveled portion of the frame to force the

door laterally outward, during the unlatching of the lock, substantially as described.

2. The combination of a door-frame, a track carried thereby, a laterally-movable door, and a lock provided with a slidable device arranged when moved outward to engage the door-frame to force the door outward and to engage the track, said device when moved inward being withdrawn from the track, substantially as described.

3. The combination of a door-frame having a beveled inner marginal portion, a track carried by the frame and arranged adjacent to the beveled portion, a slidable and laterally-movable door, a bolt upon the door, and a frame-engaging door-chilling device operatively connected with the lock and having an anti-latch-valve for engagement with the beveled portion of the frame during the unlatching of the door, and a forced portion constructed for automatic slidable engagement with the track when the door has reached the outward limit of its movement, substantially as described.

4. The combination of a door-frame having a beveled portion, a laterally-movable door having a swinging locking-bar, and a frame-engaging door-chilling device pivotally connected to the swinging locking-bar and constructed for engagement with the beveled portion of the frame during the outward swing of the locking-bar to force the door laterally outward, substantially as described.

5. The combination of a door-frame, a track, a laterally-movable door, a swinging locking-bar, and a frame-engaging door-chilling device operated by the locking-bar and arranged to engage the frame during the outward movement of the locking-bar to force the door outward, said device being also carried by such movement into engagement with the track, substantially as described.

6. The combination of a door-frame, a slidable and laterally-movable door provided at its bottom with a recess, a track located beneath the door, a hanger hinged in the recess and arranged to run on the track at the bottom of the door, an upper track, and a device arranged to move inward and outward to and from the upper track and adapted in its outward movement to engage the door-frame to move the door outward, substantially as described.

7. The combination with a door-frame having a keeper, of a laterally-movable door, a lock thereon having a slidable locking-bolt provided with a beveled outer end constructed for engagement with the keeper during the outward movement of the bolt to draw the door laterally inward, and a frame-engaging door-chilling device slidably mounted on the door and operatively connected with the lock for engagement with the frame to force the door outward, substantially as described.

700,260. THE INSTRUCTING DEVICE FOR PRINTING. FRANKLIN. JOHN THOMSON, New York, N. Y., assignor to John Thomson Press Company, New York, N. Y., a Corporation of New Jersey. Filed July 1, 1901. Serial No. 62,715. (No model.)

Claim.—In a printing-press, the combination with the change-bar, hollow screw and crescent, of the change arrow-shaft, the duplex thread, or threads, of which are cut away, as at P, to effect a relatively slow reversal of the change-bar, substantially as described.

700,261. RIVETING MECHANISM. JAMES L. THOMSON, Cayuga, N. Y., assignor to J. L. Thomson Manufacturing Company, New York, N. Y., a Corporation of New York. Filed July 11, 1901. Serial No. 67,386. (No model.)

Claim.—1. The combination of a stationary head supporting the riveting mechanism, an anvil secured to said head, a plunger guided in the head in line with the anvil, toggle-arms pivoted respectively to the head and to the plunger, a lever fulcrumed on the head and operating the toggle-arms, guides on the lever and on the head and lateral extensions on the toggle-arms engaging said guides and controlling the direction of the movement of the toggle-arms as set forth.

2. The combination of the head supporting the riveting mechanism, an anvil secured to the head adjustably for rivets of different lengths, a plunger guided in the head in line with the anvil, a rivet-supporter interposed between the plunger and anvil, toggle-arms pivoted respectively to the head and to the plunger, a lever fulcrumed on the head and operating said toggle-arms, guides on the lever and on the head and lateral extensions on the toggle-arms engaging said guides and controlling the direction of the movement of the toggle-arms as set forth.

3. The combination of the head supporting the riveting mechanism, an anvil secured to the head adjustably for rivets of different lengths, a plunger guided in the head in line with the anvil, a lever pivoted at one end to the upper part of the head, a curved guide-groove in the side of the pivoted end of the lever, a similar guide-groove in the lower portion of the head, a toggle-arm pivoted to the upper part of the head and formed at its lower end with a lateral extension terminated with a leg engaging the guide-groove in the lever, and a toggle-arm pivoted at its upper end to the lower end of the first-mentioned toggle-arm and connected at its lower end to the plunger and formed therewith with a lateral extension terminating with a leg engaging the guide-groove in the head substantially as shown and set forth.

4. The combination of the head supporting the riveting mechanism, the anvil secured to the head adjustably for different lengths of rivets, the spring-arms terminating with rivet-supporting fingers over the anvil, the plunger guided in the head in line with the anvil, the lever pivoted at one end to the upper part of the head and formed with a cam facing toward the head and with a guide-groove parallel with said cam, a guide-groove in the lower portion of the head, toggle-arms pivoted respectively to the upper part of the head and to the plunger and bearing at their junction on the cam of the lever, a lateral extension formed on the lower end of the upper toggle-arm and terminated with a leg engaging the guide-groove in the lever, and a lateral extension formed on the lower end of the lower toggle-arm and terminated with a leg engaging the guide-groove in the head, all constructed and combined as shown and set forth.

700,262. CAR-COUPLING. JAMES THOMSON, Columbus, Ohio, assignor to Buckeye Malleable Iron and Coupler Company, Columbus, Ohio. Filed June 2, 1901. Serial No. 62,792. (No model.)

Claim.—1. A connecting device for car-couplings comprising buffing-blocks adapted for removable attachment to the coupling-heads and a flexible device connecting said buffing-blocks, and permitting the front ends of said blocks to bear against each other.

2. A connecting device for car-couplings, comprising heads to be removably connected with the knuckles of the couplings, and a flexible device connecting said heads.

3. A connecting device for car-couplings comprising heads adapted to be removably attached to the knuckles of the couplings, said heads constructed to project forwardly beyond the knuckles and constitute buffers, and a connection between said heads.

4. A connecting device for car-couplings, comprising two heads adapted to be mounted on the couplings, one head constituting an abutment for the other, and a device attached at its respective ends to said heads.

5. A connecting device for car-couplings, comprising two heads adapted to be removably supported by the couplings and project beyond the same to form buffing-blocks, each head having a flaring recess in its forward end and a connector, attached at its respective ends at the base of the flaring recess in the respective heads.

6. A connecting device for car-couplings, comprising two blocks constructed to conform to the contour of the front ends of the draw-heads, each block having a portion projecting beyond the knuckle and having a buffing-flare, and a device connecting said blocks.

7. A connecting device for car-couplings, comprising buffing-blocks constructed to be removably attached to the knuckles of the draw-heads and project beyond the same and a device connecting said buffing-blocks in a manner to permit them to come together.

8. A connecting device for car-couplings comprising auxiliary heads to be removably connected with the couplings, said heads having outer buffing-flares and means connecting said heads.

9. A connecting device for car-couplings comprising auxiliary heads adapted to be removably secured to the pivoted knuckles of the couplings, and provided with buffing-flares and means connecting said heads.

10. A connecting device for car-couplings comprising removable heads each supported by a coupling, each head having a part approximately filling the space between the inner face of the knuckle and the adjacent surface of the coupling, and also provided with a buffing-flare in advance of the knuckle, and means connecting said removable heads.

700,263. BRIDGE FOR PAINT-BRUSHING. GEORGE C. TRAMER, Philadelphia, Pa. Filed July 27, 1901. Serial No. 60,362. (No model.)

Claim.—1. A bridge for brushwork comprising a strip of fabric having oppositely-blended ends and cyclists arranged adjacent to the edges of the strip and cyclists arranged adjacent to the top of the strip at the center thereof, a hawing wire or cord attached to one end of the bridge-strip and adapted to be passed through the cyclists for the purpose of drawing the ends of the bridge-strip together, and a staple for fastening the opposite end of the wire to the brush-head, and a wire passing through the central cyclists and a staple for securing the said wire to the brush-head, substantially as set forth.

2. A bridge for brushwork comprising a strip having oppositely-blended ends and provided with cyclists adjacent to the said ends and the cyclists adjacent to the upper edge of the strip at the center of the same, an underlapping strip attached to one end of the bridge-strip, a hawing-wire being adapted to be passed through the end cyclists for the purpose of drawing the ends of the bridge-strip together, a staple for securing the opposite end of said hawing-wire, and a wire adapted to be passed through the central cyclists, the ends of the wire being secured to the brush-head by means of a staple, substantially as shown and described.

700,264. ROLL-HOLDING CAMERA. RALPH E. THOMSON, Chicago, Ill. Filed May 2, 1901. Serial No. 59,360. (No model.)

Claim.—1. In a camera, a spindle adapted to pass longitudinally through the film-spool and form the axis of rotation thereof, and a bracket supported upon one of the walls of the camera-box and adapted to be adjusted upon said bar to accommodate various sizes of spoils; substantially as described.

2. In a camera, the combination with a rotatable spindle, of a bracket adapted to support the film-spool, secured to the camera-box and longitudinally adjustable upon said spindle, non-rotatable with respect thereto and a clutch sliding upon said spindle, non-rotatable with respect thereto and engaging the spindle; substantially as described.

3. In a camera, the combination with a vertically-adjustable bracket adapted to support the film-spool, of a spindle forming the axis of rotation of said spool, and extending without the camera in the form of a knob by means of which the spool may be rotated, a clutch longitudinally movable upon said spindle but non-rotatable with respect thereto, and adapted to positively engage the spool, and a spring to hold said clutch in engagement with the spool; substantially as described.

4. In a camera, the combination with a camera-box, of a spindle adapted to receive the film-spool, a bracket for supporting the spindle, a screw-threaded pin secured in the bracket and extending out through a suitable slot in the wall of the box, and a nut upon the end of the pin to covering the bracket in place; substantially as described.

700,265. CART-TRUCK. BENJAMIN W. TUCKER, Newark, N. J. assignor to Edward G. Newark, N. J. Filed Mar. 13, 1902. Serial No. 59,374. (No model.)

Claim.—1. In a cart-truck, the angle-iron upper and lower transverse-beams 13, 14, secured at their ends to the side frames with a free space left intermediate these portions of the vertical flanges of said beams disposed intermediate the side frames, the horizontal flanges of said upper and lower transverse-beams being projected in opposite directions; substantially as set forth.

2. In a cart-truck, the angle-iron upper and lower transverse-beams 13, 14, secured at their ends to the side frames with a free space left intermediate these portions of the vertical flanges of said beams disposed intermediate the side frames, the horizontal flanges of said upper and lower transverse-beams being projected in opposite directions, combined with plates interposed between the upper and lower bars of said side frames and secured to the vertical flanges of said beams; substantially as set forth.

3. In a cart-truck, the side frames having the upper and lower bars, the angle-iron upper and lower transverse-beams 13, 14, secured at their ends to said bars, and outer plates 15 secured to the vertical flanges of said beams intermediate said bars, combined with the inner plates 16 affording proper surfaces for the bolsters and connected by rivets or bolts with said outer plates; substantially as set forth.

4. In a cart-truck, the side frames having the upper and lower bars, the angle-iron upper and lower transverse-beams 13, 14, secured at their ends to said bars, and plates secured to and connecting the vertical flanges of said beams, combined with the caps 22 for sliding in securing the beams 13 to said upper bar, and bolts 23 passing through said caps, said upper bar and said transverse, said caps being recessed at their upper side to pass upon the edges of said upper bar and recessed at their lower side to receive the ends of said beams 13; substantially as set forth.

5. In a cart-truck, the side frames having the upper and lower bars, and the angle-iron upper and lower transverse-beams 13, 14, secured at their ends to said bars, combined with the base-block 30 recessed at its upper side to receive the said beams 14 and at its lower side to engage the lower bar of the side frame, and bolts 22 passing through said lower bar, said base-block and said beams 14; substantially as set forth.

6. In a cart-truck, the side frames having the upper and lower bars, and the angle-iron upper and lower transverse-beams 13, 14, secured at their ends to said bars, combined with the base-block 30 recessed at its upper side to receive the said beams 14 and at its lower side to engage the lower bar of the side frame, bolts 22 passing through said lower bar, base-block and beams 14, and the plate 34 mounted upon said base-block and affording a cushion for the bolsters, said plate 34 being recessed to receive the heads of said bolts 22, the latter being thereby secured to said base-block and plate in position; substantially as set forth.

7. In a cart-truck, the angle-iron upper and lower transverse-beams 13,

14, secured at their ends to the side frames with a free space left intermediate these portions of the vertical flanges of said beams disposed intermediate the side frames, the horizontal flanges of said upper and lower transverse-beams being projected in opposite directions, combined with plates interposed between the upper and lower bars of said side frames and secured to the vertical flanges of said beams, said plates having extensions projecting inward laterally beyond the side frames and secured to the vertical flanges of said transverse-beams; substantially as set forth.

8. In a cart-truck, the angle-iron upper and lower transverse-beams 13, 14, secured at their ends to the side frames with a free space left intermediate these portions of the vertical flanges of said beams disposed intermediate the side frames, the horizontal flanges of said upper and lower transverse-beams being projected in opposite directions, and the ends of said free space being curved and adjacent to said side frames; substantially as set forth.

9. In a cart-truck, the side frames having the upper and lower bars, parallel upper transverse-beams secured at their ends to said upper bars and having horizontal members projecting toward the ends of the truck, and parallel lower transverse-beams secured at their ends to the lower bars of the side frames and having horizontal members projecting toward the transverse center of the truck, the inner edges of the upper beams being about on a vertical line with the outer edges of the lower beams, combined with plates connecting the said upper and lower transverse-beams at their ends and portions at each side of the center of the side frames, leaving a clear space for the bolsters and its parts; substantially as set forth.

700,266. ROCKING-CHAIR. CARL H. WAGNER, Chicago, Ill. Filed Jan. 4, 1902. Serial No. 59,377. (No model.)

Claim.—1. In a folding rocking-chair, the combination with a seat-frame and a back-frame pivotally connected together, of a pair of rockers, a pair of rear braces pivoted at their lower ends to the rockers and pivotally connected near their upper ends with the seat-frame near the rear end thereof, a second pair of braces pivoted at their lower ends to the rockers, forward of said first-named braces, and pivotally connected at their upper ends with the back-frame, each last-named pivotal connection being in rear of the pivotal connection of the first-named braces with the seat-frame when the chair is in position for use, means for limiting the backward movement of said second-named pair of braces, and a movable brace extending from each of said second-named pair of braces to the seat-frame, substantially as specified.

2. In a folding rocking-chair, the combination with a seat-frame and a back-frame pivotally connected together, of a pair of rockers, a pair of rear braces pivoted at their lower ends to the rockers and pivotally connected near their upper ends with the seat-frame near the rear end thereof, a second pair of braces pivoted at their lower ends to the rockers, forward of said first-named braces, and pivotally connected at their upper ends with the back-frame, each last-named pivotal connection being in rear of the pivotal connection of the first-named braces with the seat-frame when the chair is in position for use, a stop to limit the forward movement of the said second-named pair of braces, and a movable support for the front portion of the seat-frame, substantially as specified.

3. In a folding rocking-chair, the combination with a seat-frame and a back-frame pivotally connected together, of a pair of rockers, a pair of rear braces pivoted at their lower ends to the rockers and pivotally connected near their upper ends with the seat-frame near the rear end thereof, a second pair of braces pivoted at their lower ends to the rockers, forward of said first-named braces, and pivotally connected at their upper ends with the back-frame, each last-named pivotal connection being in rear of the pivotal connection of the first-named braces with the seat-frame when the chair is in position for use, steps formed by the projecting upper ends of said first-named pair of braces, against which the second-named pair of braces are adapted to come in contact, and a movable support for the front portion of the seat-frame, substantially as specified.

4. In a folding chair, the combination of a seat-frame, a back-frame pivotally connected therewith, a pair of rear braces pivotally connected near their upper ends with the seat-frame, near the rear end thereof, a pair of front braces pivotally connected at their upper ends with the back-frame, means for limiting the backward movement of said pair of front braces, braces connecting the front portion of the seat-frame with said front braces, and means for preventing the lower portions of said front and rear braces from spreading, substantially as described.

5. In a folding chair, the combination of a seat-frame, a back-frame pivotally connected therewith, a pair of rear braces pivotally connected near their upper ends with the seat-frame, near the rear end thereof, a pair of front braces pivotally connected at their upper ends with the back-frame, means for limiting the backward movement of said pair of front braces, braces connecting the front portion of the seat-frame with said front braces, and means connecting the front and rear braces at each side of the chair together, substantially as described.

6. In a folding chair, the combination of a seat-frame, a back-frame pivotally connected therewith, a pair of rear braces pivotally connected near their upper ends with the seat-frame, near the rear end thereof, a pair of front braces pivotally connected at their upper ends with the back-frame, means for limiting the backward movement of said pair of front braces, braces connecting the front portion of the seat-frame with said front braces, and means pivotally connecting the front and rear braces at each side of the chair together, substantially as described.

7. In a folding chair, the combination of a seat-frame, a back-frame pivotally connected therewith, a pair of rear braces pivotally connected near their upper ends with the seat-frame, near the rear end thereof, a pair of front braces pivotally connected at their upper ends with said back-frame, the upper ends of said front braces extending above the upper ends of said rear braces when the chair is in position for use, means for limiting the backward movement of said pair of front braces, braces connecting the front portion of the seat-frame to said front braces, and means connecting the lower portions of the front and rear braces at each side of the chair, substantially as described.

8. In a folding chair, the combination of a seat-frame, a back-frame pivotally connected therewith, a pair of rear braces pivotally connected near their upper ends with the seat-frame, near the rear end thereof, a pair of front braces pivotally connected at their upper ends with the back-frame, means for limiting the backward movement of said pair of front braces, braces connecting the front portion of the seat-frame with said front braces, and rockers pivotally connected to the front and rear braces at each side of the chair, substantially as described.

700,267. DOCUMENT-FILE. EDWARD S. WATSON, New York, N. Y. Filed Mar. 24, 1901. Serial No. 59,368. (No model.)

Claim.—1. A filing-back for documents, provided with a spring-clip having spring-guides extending from the clip approximately along at least one edge of the said back for guiding the papers, substantially as set forth.

2. A temporary back for filing documents, provided with a clip, one member of which is movable relatively to the said back and provided with means for pressing and securing the documents along a diagonal line, and spring-guides extending between the said clip member and the said back, substantially as set forth.

700,968. CHEMICAL APPARATUS. JOHN A. WHITMAN, Chicago, Ill. Filed Oct. 20, 1891. Serial No. 93,593. (No model.)

Claim.—1. A chemical apparatus comprising a condenser; a chamber communicating with said condenser and having a tubular extension; a resilient sleeve mounted on said extension and forming therewith a hollow stopper; and a steam-pipe entering said extension above the stopper part, passing out through the interior of the stopper, and having a valve outward of its entering part.

2. A chemical apparatus comprising a condenser; a chamber communicating with said condenser and having a tubular extension; a resilient sleeve mounted on said extension and forming therewith a hollow stopper; a receptacle outside of said extension having a pipe entering said extension above the stopper part, passing out through the interior of the stopper; and a steam-pipe entering said extension above the stopper part, passing out through the interior of the stopper, and having a valve outward of its entering part.

3. A chemical apparatus comprising a condenser; a chamber communicating with said condenser and having a tubular extension; a resilient sleeve mounted on said extension and forming therewith a hollow stopper; a steam-pipe entering said extension above the stopper part, passing out through the interior of the stopper, and having a valve outward of its entering part; and an outer clamp adapted to coast with said stopper in engaging and supporting a flask.

4. A chemical apparatus comprising a condenser; a rigid pipe extending downwardly and outwardly from said condenser and rigidly supporting a chamber at its outer end; said chamber having a depending tubular extension provided with a resilient sleeve forming therewith a hollow stopper; a clamp secured to the lower part of said condenser and having jaws acting toward the side of said stopper and adapted to coast with said stopper in engaging and supporting a flask; a receptacle outside of said extension having a pipe entering said extension above the stopper part, and passing out through the interior of the stopper, and having a valve controlling the passage through said pipe; and a steam-pipe entering said extension above the stopper part, passing out through the interior of the stopper, and having a valve outward of its entering part.

5. A chemical apparatus comprising a chamber having an outlet-passage in its side, said chamber having a neck extending above same adapted to receive a stopper; a depending tubular extension on said chamber having on its lower end a resilient sleeve forming therewith a stopper;

a flask removably fitting the stopper end of said extension; a receptacle above said neck having a pipe passing through said neck and tubular extension to the bottom of the flask and having a valve above said neck controlling the passage through said pipe; a stopper securing said pipe in said neck; and a second pipe, independent of the outlet-passage and independent of the other pipe and said receptacle, entering said extension above the stopper part of same, passing through the interior of said extension to the bottom of the flask, and having a valve outward of its entering part.

6. A chemical apparatus comprising a suitably supported condensing-tank, a condensing-coil therein having a supply-pipe extending outwardly and downwardly from said tank, the chamber 6, pipe 7 and chamber 8 rigidly connected and supported by said tank in the relative positions shown, said chamber 6 having a depending tubular extension, and a resilient sleeve mounted on said extension and forming therewith a hollow stopper adapted to engage and support a distillation-flask substantially as shown.

700,969. STREET-CAR FENDER. CHARLES C. WINE, Kansas City, Mo., assignor of one-half to James R. Lockwood, Kansas City, Mo. Filed Nov. 1, 1891. Serial No. 93,778. (No model.)

Claim.—1. A street-car fender, comprising a curved track, pivoted to operate vertically, a box mounted to slide thereon transversely of the car-track, a fender-frame rigidly connected to said box, a basket secured to the front end of the axle, journal-bones secured near the rear end of said frame, an axle journaled in said bones, and wheels mounted on said axle, and adapted to travel upon the car-track rails, substantially as described.

2. A car-fender, comprising a slotted segmental tubular track pivoted to operate vertically, a box mounted on said track, and provided with rollers engaging the same internally and externally, the transverse of said internal rollers projecting through the slots of the track, and a wheel-supported frame rigidly secured to said box and provided at its front end with a basket, substantially as described.

3. A car-fender, comprising a slotted segmental tubular track adapted for connection with a car, a box upon said track, rollers journaled in said box and within the track, rollers journaled in said box and engaging the front or rear sides of the track, and a wheel-supported frame secured to said box and provided with a basket at its front end, substantially as described.

4. A car-fender, comprising a curved track, pivoted to work vertically, a box slidably mounted on the track, a wheel-supported frame provided with a basket at its front end, and a cross-bar at its rear end having a curved portion fitting against the front side of the box, an arched brace connecting the side of the wheel-supported frame, rollers-plates secured to the ends of the box and having depending arms engaging the front side of the cross-bar of the wheel-supported frame, and plates secured to the upper and lower sides of the box and provided with braces-

arms connected at their front ends to the middle of said arched brace, one of said plates having a vertical portion bearing against the front side of said cross-bar of the wheel-supported frame, substantially as described.

5. A car-fender, comprising a curved track pivoted to the car to work vertically, a box slidably mounted thereon, a wheel-supported frame connected at its rear end to said box, an arch connecting the side of said frame near its front end, a brace connecting the center of said arch with the front end of said frame and depressed near its front end to a plane below that of the wheel-supported frame, and a basket secured upon said arch and that portion of the wheel-supported frame in advance of the arch and overlying said brace, substantially as described.

6. A car-fender, comprising a curved track pivoted in the car to work vertically, a box slidably mounted on said track, a wheel-supported frame secured at its rear end to said box and provided at its front end with a basket, longitudinal braces for said wheel-supported frame, provided with openings, journal-bones fitting in said openings, and having vertical movement with relation thereto, an axle journaled in said journal-bones and wheels mounted on said axle, and adapted to run upon the car-track, substantially as described.

700,970. MEANS FOR LUBRICATING HYDRAULIC CYLINDERS. LOUIS E. H. WINE, Baltimore, Md., assignor of one-half to R. E. Moore, Baltimore, Md. Filed July 20, 1891. Serial No. 73,857. (No model.)

Claim.—The combination with a hydraulic cylinder and the supply-pump having a pipe supply connection thereto, of an oil cup or receptacle, a pipe connection from one end of said cup to the hydraulic cylinder, and an independent pipe connection from the other end of said cup to said supply-pump, substantially as described.

700,971. RULING-MACHINE. ARTHUR H. WHITMAN, West Medford, Mass., assignor to Library Bureau, Boston, Mass., a Corporation of Massachusetts. Filed Aug. 31, 1891. Serial No. 73,967. (No model.)

Claim.—1. In a ruling-machine, the combination of a blank-conveyor, a penholder and a stop-gate relatively adjustable one to the other and each movable to and from the conveyor, the stop-gate behind the penholder, pens carried by the penholder, means for intermittently moving the penholder and the stop-gate to and from the conveyor, and mechanical connections whereby the movements of the stop-gate to and from the conveyor are made to precede the movements of the penholder to and from the conveyor, respectively.

2. In a ruling-machine, the combination of a blank-conveyor, a penholder and a stop-gate relatively adjustable one to the other and each movable toward and from the conveyor, the stop-gate behind the penholder, pens carried by the penholder, adjustable means for intermittently moving the penholder and the stop-gate to and from the conveyor, whereby the movements of the stop-gate to and from the conveyor are made to precede the movements of the penholder to and from the conveyor, respectively.

3. In a ruling-machine, the combination of a blank-conveyor, a penholder and a stop-gate, each movable to and from the conveyor, the stop-gate behind the penholder, pens carried by the penholder, means for intermittently moving the penholder and the stop-gate to and from the conveyor, a front gate, situated in front of the penholder, means for moving the front gate to and from the conveyor, and mechanical connections whereby the movements of the stop-gate to and from the conveyor are made to precede the movements of the penholder to and from the conveyor, respectively, the front gate being timed to move from the conveyor before the stop-gate descends thereon, by an interval not greater than the time occupied by a point on the conveyor in passing from the front gate to the stop-gate.

4. In a ruling-machine, the combination of blank-conveyor, a penholder and a stop-gate, each movable to and from the conveyor, the stop-gate behind the penholder, pens carried by the penholder, means for in-

termittently moving the penholder and the stop-gate to and from the conveyor, a front gate, situated in front of the penholder, adjustable means for intermittently moving the penholder, stop-gate, and front gate to and from the conveyor, whereby the movements of the stop-gate to and from the conveyor are made to precede the movements of the penholder to and from the conveyor, respectively, the front gate being timed to move from the conveyor before the stop-gate descends thereon, by an interval not greater than the time occupied by a point on the conveyor in passing from the front gate to the stop-gate.

5. In a ruling-machine, the combination of a blank-conveyor, a penholder, a stop-gate, a carriage therefor movable and adjustably mounted on the machine-frame, the stop-gate behind the penholder, pens carried by the penholder, means for intermittently moving the penholder and the stop-gate to and from the conveyor, and mechanism whereby the movements of the stop-gate to and from the conveyor are made to precede the movements of the penholder to and from the conveyor, respectively.

6. In a ruling-machine, the combination of a blank-conveyor, penholder and pens, stop-gate, adjustable supporting-bar therefor, brackets for said bar, adjustable actuating-link for the stop-gate, pen-arms and stop-gate arms, and connections therefrom to the penholder and stop-gate, respectively, whereby the movements of the stop-gate and penholder are made to alternate, substantially as described.

7. In a ruling-machine, the combination of a blank-conveyor, a penholder and a stop-gate, each movable to and from the conveyor, the stop-gate behind the penholder, pens carried by the penholder, and a side gate provided with a leading-in guide and a straightening edge, located over the conveyor close to the same end in front of the stop-gate.

700,972. SPINNING. JAMES WINNER, New Hartford, Conn. Filed Apr. 12, 1891. Serial No. 54,005. (No model.)

Claim.—1. An improved thread-guide for a spinning-machine comprising an annular body part and two arms, on the body part of the guide, located substantially opposite to each other on said body part.

2. In combination in a ring-spinner, a ring supported in operative relation to a spindle and having a groove in its inner surface, and a thread-guide located in said groove with a plural number of arms, located opposite to each other and projecting from the body part of the guide and with eyes or loops for the passage of the thread.

3. An improved thread-guide for a spinning-machine comprising an annular body part and a plural number of arms projecting on opposite sides thereof, one arm being longer than the other on the opposite side of the body part, and eyes or loops formed in the arms for the passage of a thread.

700,373. RADDER, EDWIN R. WHEARE, Attleboro Falls, Mass., assignor to V. E. Washburn and Company, Attleboro Falls, Mass., a firm composed of Edwin W. Washburn and Edwin R. Wheare. Filed Feb. 17, 1902. Serial No. 94,413. (No model.)

Claim.—1. A hedge comprising a frame having a central portion separated along its upper and lower edges from the main body and bent back from the surface plane of said main body, and projections extending rearwardly from the frame below said central portion.

2. A hedge comprising an ornamental frame portion having a recessed panel open along its upper and lower edges and connected at its ends to the frame portion and rearwardly-extending projections formed in the material of the frame below said panel.

3. A hedge comprising an ornamental frame, having a recessed panel open along its upper and lower edges, projections or supports extending rearwardly from the frame below said panel, and a filling inserted through the open edges of the panel and supported on said projections.

4. A hedge comprising a frame, having a recessed panel open along its upper and lower edges and connected at its ends with the frame portion, and a fastening-pin secured to the back of the frame above said panel.

5. A hedge comprising a frame, having a recessed panel open along its upper and lower edges and connected at its ends with the frame portion, a fastening device arranged on the frame above said panel, and a ribbon having its upper portion looped over the panel and secured.

6. The combination with the frame 5 having the back plate 6 separated therefrom along its upper and lower edges and connected at its ends and the rearwardly-extending projections 10 10 of the ribbon 14 secured to said back plate 6 as described, and the transparent protective medium 15 extending through the openings between the back plate and the frame and supported on the projections 10 10.

700,374. LACE HOOK AND CLASP. HERBERT R. WILSON, Rochester, N. Y. Filed Sept. 20, 1901. Serial No. 75,864. (No model.)

Claim.—1. A lace hook and clasp consisting of a cap-piece articulating with an eyelet, each eyelet and cap-piece connected together by means of a stem hinged to each cap-piece, and a spring operating to hold each cap-piece relatively to each stem either in its open or closed position as desired, each cap-piece carrying two projections arranged to mesh on each side of each stem.

2. A lace hook and clasp consisting of a cap-piece articulating with an eyelet, each eyelet and cap-piece connected together by means of a stem hinged to each cap-piece, and a spring operating to hold each cap-piece relatively to each stem either in its open or closed position as desired, a discontinuous flange on each cap-piece with the two ends thereof arranged to mesh on each side of each stem.

700,375. CRUDE-OIL BURNER. NORMAN T. WILSON, Fort Worth, Tex. Filed Apr. 22, 1901. Serial No. 68,985. (No model.)

Claim.—1. The improved oil-burner, comprising a series of superposed shelves having an air-space between them, each shelf having oil-passages formed in it, whereby oil will be distributed, and suitable supports for holding said shelves in position, said shelves all being hinged at one edge, and means for securing the opposite edges of said shelves, substantially as specified.

2. The improved oil-burner, comprising a series of superposed shelves having an air-space between them, each shelf having oil-passages formed in it, whereby oil will be distributed, suitable supports for holding said shelves in position, said shelves being hinged at one edge, a rod,

and a series of screws for securing the opposite edges of said shelves, substantially as specified.

3. The improved oil-burner, comprising a series of superposed shelves having an air-space between them, each shelf having oil-passages formed in it, whereby oil will be distributed, suitable supports for holding said shelves in position, said shelves all being hinged at one edge, means for securing the opposite edges of said shelves, and a distributing-pipe mounted upon the upper shelf, substantially as specified.

700,376. COOLING MEANS FOR ROTARY MOTORS. LISA WILSON, Brooklyn, N. Y. Filed July 26, 1901. Serial No. 68,719. (No model.)

Claim.—1. In a rotary motor driven by highly-heated gas, the combination, with the motor-wheel, of a casing having a peripheral water-jacket and a supply, to the points of proximity of the wheel and casing, of pure or distilled water which will not deposit a crust or scale.

2. In a rotary motor driven by highly-heated gas, the combination, with the motor-wheel, of a casing having the cheeks or channels A arranged to form guides for the edges of the motor-wheel disks to revolve in, and each channel being provided with a supply of cooling fluid, substantially as herein set forth.

3. In a rotary motor driven by highly-heated gas having a revolving motor-wheel provided with return-disks, the combination therewith of channels or guides in which the edges of said exhaust-disks revolve, each channel provided with a cooling fluid, substantially as herein set forth.

4. In a rotary motor, the combination, of the exhaust-jacket a and the casing f, and the primary motor-blades c with channels or guides for the disks of the motor-wheel to revolve in, the disks 1, 3 and 5 closely secured to the shaft, the other disk or disks secured to the shaft by arms permitting the passage of gas between them, the blades secured to their respective disks, and means for projecting cooling fluid upon the various parts, substantially as and for the purposes set forth.

5. In a rotary motor, the combination of the exhaust-jacket a, the return or exhaust blades c, and the casing f, and the primary motor-blades c with channels or guides for the disks of the motor-wheel to revolve in, the disks 1, 3 and 5 in a wheel provided with return or exhaust blades, closely secured and disk 3 in a wheel without return or exhaust blades, closely secured

to the shaft, the other disk or disks secured to the shaft by arms permitting the passage of gas between them, the blades secured to their respective disks, the curved spaces i applied to the shaft between it and the inner ends of the blades to guide the exhaust-gas from the primary motor-blades c around the space toward the exhaust-jacket or toward the inner ends of the return-blades c, if the wheel is provided with return-blades, the gas passing through these blades to the exhaust-jacket a and means for projecting a cooling fluid upon the various parts, substantially as herein set forth.

6. In a rotary motor, the combination of the exhaust-jacket a, the return or exhaust blades c, and the casing f, a water-jacket and the primary motor-blades c with channels or guides for the disks of the motor-wheel to revolve in, the disks 1, 3 and 5 in a wheel provided with return or exhaust blades, and disk 3 in a wheel without return or exhaust blades, closely secured to the shaft, the other disk or disks secured to the shaft by arms permitting the passage of gas between them, the blades secured to their respective disks, and pipes provided to deliver cooling fluid to the various parts, substantially as herein described.
